RESPONSE SOLUTIONS TO QUASI-PERIODICALLY FORCED SYSTEMS, EVEN TO POSSIBLY ILL-POSED PDES, WITH STRONGLY DISSIPATION AND ANY FREQUENCY VECTORS

FENFEN WANG AND RAFAEL DE LA LLAVE

Abstract. We consider several models (including both multidimensional ordinary differential equations (ODEs) and partial differential equations (PDEs), possibly ill-posed), subject to very strong damping and quasi-periodic external forcing. We study the existence of response solutions (i.e., quasi-periodic solutions with the same frequency as the forcing). Under some regularity assumptions on the nonlinearity and forcing, without any arithmetic condition on the forcing frequency $\omega$, we show that the response solutions indeed exist. Moreover, the solutions we obtained possess optimal regularity in $\varepsilon$ (where $\varepsilon$ is the inverse of the coefficients multiplying the damping) when we consider $\varepsilon$ in a domain that does not include the origin $\varepsilon = 0$ but has the origin on its boundary. We get that the response solutions depend continuously on $\varepsilon$ when we consider $\varepsilon$ tends to 0. However, in general, they may not be differentiable at $\varepsilon = 0$. In this paper, we allow multidimensional systems and we do not require that the unperturbed equations under consideration are Hamiltonian.

One advantage of the method in the present paper is that it gives results for analytic, finitely differentiable and low regularity forcing and nonlinearity, respectively. As a matter of fact, we do not even need that the forcing is continuous. Notably, we obtain results when the forcing is in $L^2$ space and the nonlinearity is just Lipschitz as well as in the case that the forcing is in $H^1$ space and the nonlinearity is $C^{1,\text{Lip}}$.

In the proof of our results, we reformulate the existence of response solutions as a fixed point problem in appropriate spaces of smooth functions. Based on the fixed point problem, we will obtain response solutions as well as some regularity with respect to the singular perturbation parameter $\varepsilon$ except at the origin $\varepsilon = 0$. More precisely, in the analytic case, we use the contraction mapping principle to get response solutions analytic in $\varepsilon$ for $\varepsilon$ in a complex domain. In the highly differentiable case, to obtain optimal regularity in $\varepsilon$, we combine with the classical implicit function theorem. In the low regularity case, such as $H^1$, the contraction argument we use will be somewhat more sophisticated. Particularly, we do not use dynamical properties of the models, so the method applies even to ill-posed equations and we give some examples.

Keywords. Strong dissipation; Response solutions; Singular perturbations.

1. Introduction

In recent times, there has been much interest in the study of response solutions for nonlinear mechanical models subject to strong dissipation and quasi-periodic external forcing. We recall that response solutions are solutions with the same frequency as the forcing. The mechanical systems are second order equations. Since the large coefficients of dissipation are factors of terms involving the first derivative, this is a singular perturbation.

We are interested in finding response solutions for two kinds of equations. We first consider an ODE model of the form:

\[ x_{tt} + \frac{1}{\varepsilon} x_t + g(x) = f(\omega t), \quad x \in \mathbb{R}^n. \]  

The equation (1.1) is referred as “varactor” equations in the literature [CCdlL13, Gen10a, CFG14, GMV17, GV17].

We also consider PDE models. One particular example is obtained from the Boussinesq equation (derived in the paper [Bou72]) by adding a singular friction proportional to the velocity:

\[ u_{tt} + \frac{1}{\varepsilon} u_t - \beta u_{xxxx} - u_{xx} = (u^2)_{xx} + f(\omega t, x), \quad x \in \mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}, \quad \beta > 0, \]  

where \( \beta > 0 \) is a parameter. Of course, the equation (1.2) will be supplemented with periodic boundary conditions. We note that the positive sign of \( \beta \) makes equation (1.2) ill-posed. That is, there are many initial conditions that do not lead to solutions. It is, however, possible that there is a systematic way to construct many special solutions, for some ill-posed Boussinesq equations, which are physically observed (we refer to the papers [dlLS19, dlL09, CdlL19a, CdlL19b]).

In both equations (1.1) and (1.2), \( \varepsilon \) is a small parameter in \( \mathbb{R} \) and \( \omega \in \mathbb{R}^d \) with \( d \in \mathbb{N}_+ := \mathbb{N} \backslash \{0\} \). The forcing \( f \) is quasi-periodic with respect to time \( t \). Note that in the PDE (1.2), the forcing may depend on the space variable. At this moment, we think of the forcing as a quasi-periodic function taking values in a space of functions.

In equation (1.1), one considers the nonlinearity \( g \) as a function from \( \mathbb{R}^n \) to \( \mathbb{R}^n \) with \( n \in \mathbb{N}_+ \) and the forcing \( f \) as a function from \( \mathbb{T}^d \) to \( \mathbb{R}^n \). We will obtain several results depending on the regularity assumed for \( f \) and \( g \). First, we will consider that the functions \( f \) and \( g \) are real analytic such that they take real values for real arguments, which are what appears in physical applications, with \( \varepsilon \in \mathbb{R} \). We will also consider highly differentiable functions \( f \) and \( g \), such as \( f \in H^m(m > \frac{d}{2}) \) and \( g \) is \( C^{m+l} \), \( l = 1, 2, \ldots \). In addition, we will obtain results for rather irregular functions \( f \) and \( g \). For example, the forcing \( f \) is in the \( L^2 \) space, the nonlinearity \( g \) is just Lipschitz or \( f \) is in the \( H^1 \) space, \( g \) is \( C^{1+\text{Lip}} \).

In equation (1.2), we consider the function \( f : \mathbb{T}^d \times \mathbb{T} \to \mathbb{R} \). Analogously to the case of (1.1), we will present results for \( f \) being real analytic and finitely differentiable with high regularity. Note that in the study of the PDE model (1.2), we will just focus in the physically relevant case of a specific nonlinearity \( (u^2)_{xx} \). It is possible to discuss general nonlinearities in a regularity class, but being unaware of a physical motivation, we leave these generalizations to the readers. We emphasize that, in (1.2), the nonlinearity \( (u^2)_{xx} \) is unbounded from one space to itself, but
the fixed point problem we consider overcomes this problem since there will be smoothing factors.

From the point of physical view, the parameter $\varepsilon$ is real. However, it is natural to consider $\varepsilon$ in a complex domain when we consider our problem in an analytic setting. It is important to notice that the complex domain we use does not include the origin but accumulates on it. Indeed, the solutions fail to be differentiable at $\varepsilon = 0$ in the generality considered in the present paper (see Remark 16). However, we will show that the response solutions depend continuously on $\varepsilon$ as $\varepsilon$ tends to 0.

1.1. Some remarks on the literature. The problem of the response solutions for dissipative systems has been studied by several methods. One method is based on developing asymptotic series and then show that they can be resummed using combinatorial arguments, which are established using the so-called “tree formalism”. This can be found in the literature [GBD05, GBD06, Gen10b, Gen10c]. Recent papers developing this method are [GMV17, GV17]. We point out that one important novelty of the papers [GMV17, GV17] is that no arithmetic condition is required in the frequency of the forcing. A later method is to reduce the existence of response solutions to a fixed point problem, which is analyzed in a ball in an appropriate Banach space, centered in the solution predicted by the asymptotic expansion. In this direction, we refer to [CCdlL13, CCCdlL17] and references there. Note that the papers [CCdlL13, CCCdlL17] considered the perturbative expansion to low orders on $\varepsilon$ and obtains a reasonably approximate solutions in a neighborhood of $\varepsilon = 0$. Nevertheless, to obtain the asymptotic expansions, one needs to solve equations involving small divisors and assume some non-degeneracy conditions. Note that the small divisors assumed in [CCdlL13, CCCdlL17] are weaker than the Diophantine conditions in KAM theory. In this paper, we will not assume any small divisors conditions since we do not attempt to get the approximate solution through an asymptotic expansion.

Since the literature is growing, it is interesting to compare systematically results. There are several figures of merit for results on the existence of response solutions.

(1) The arithmetic properties required in the external forcing frequency, such as Diophantine condition, Bryuno condition, or even weaker conditions, etc.
(2) The analyticity domain in $\varepsilon$ established. Since we do not expect that the asymptotic series converges, this domain does not include a ball centered at the origin. Note that the shape of this analyticity domain is very important to study properties of the asymptotic series. For example, Borel summability in [GBD05, GBD06]. In the generality we consider in this paper, the solutions we construct fail to be even differentiable at the origin $\varepsilon = 0$. (See Remark 16).
(3) Whether the method gives some asymptotic expansions for the solutions.
(4) Whether the method can deal with the forcing function $f$ which has low regularity (e.g. $f \in L^2$ or $f \in H^1$) and the nonlinearity function $g$ of low regularity (the case of piecewise differentiable functions appears in some applications).
(5) The generality of the models considered (e.g. whether the method requires that the system is Hamiltonian, Reversible, etc.)
(6) Smallness conditions imposed on functions $f$ and $g$. 
Notice that all these figures of merit cannot be accomplished at the same time. Obtaining more conclusions on the solutions (e.g. the existence of asymptotic expansions) will require more regularity and some arithmetic conditions on the frequency.

1.2. The method in the present paper. From the strictly logical point of view, our paper and [GMV17, GV17] are completely different even if they are motivated by the same physical problem for the model (1.1). More precisely, the present paper deals with not only analytic problems but also finitely differentiable problems and even just Lipschitz problems by the method of fixed point theorem. In contrast, the papers [GMV17, GV17] apply resummation methods to establish the existence of response solutions under analytic condition.

In the multidimensional case in equation (1.1), compared with [GMV17], the methods presented in this paper do not need that the oscillators without dissipation are Hamiltonian or that the linearization of $g$ at the origin (i.e. $Dg(0)$, which is a $n \times n$ matrix) is positive definite. Further, we do not assume that the matrix $Dg(0)$ is diagonalizable or symmetric. We allow Jordan blocks that appear naturally in problems at resonance [BG15, Gaz15].

However, we note that our method for analytic case involves smallness assumptions in the forcing $f$ but not in the nonlinear part $\hat{g}$ of $g$. In the case of $L^2$ and $H^1$, we involve just smallness assumptions on $\hat{g}$ but not $f$. For the highly differentiable case (i.e. $H^m$, $m > \frac{d}{2}$), we choose either smallness assumption for $f$ or $\hat{g}$. (See Section 2.4).

As a further application, we consider adding dissipative terms to the Boussinesq equation of water waves in (1.2). We note that the equation (1.2) is ill-posed and not all initial conditions lead to solutions. Nevertheless, we construct special solutions which are response.

The approach followed in [CCdlL13, CCCdlL17] for similar problems (1.2) has two steps. In the first step, one constructed series expansions in $\varepsilon$ that produced approximate solutions. In a second step, one used a contraction mapping principle for an operator defined in a small ball near the approximate solutions obtained in the first step. Of course, this approach requires a very careful choice of the spaces in which the approximate solutions lie and the fixed point problems are formulated. One important consideration is that the spaces are chosen such that the operators involved map the spaces into themselves. Since some of the operators involved are diagonal in Fourier series, it is important that the norms can be read off from the Fourier coefficients. It will also be convenient that we have Banach algebras properties and that the nonlinear composition operators can be readily estimated. We have to say that it is the idea in [CCdlL13, CCCdlL17] that inspires our present treatment for the equations (1.1) and (1.2).

To motivate the procedure adopted in this paper, we note that in the method of [CCdlL13, CCCdlL17], the fixed point part does not depend on any arithmetic condition on the forcing frequency. We will modify slightly the fixed point part to get response solutions with some regularity for our model (1.1). In this way, we first reformulate the existence of response solutions for equation (1.1) as a fixed point problem. Then, under certain regularity assumptions for the nonlinearity and the forcing, we obtain the response solutions with corresponding regularity on $\varepsilon$ when $\varepsilon$ ranges over an appropriate domain without any circle centered at the origin $\varepsilon = 0$. It is quite possible that the response solutions constructed are not
differentiable with respect to $\varepsilon$ at $\varepsilon = 0$ (see Remark 16) since we do not assume any Diophantine conditions for the frequency $\omega$. Therefore, when we consider $\varepsilon$ goes to 0, we just get the response solutions depend continuously on $\varepsilon$.

The method of the proof in this paper (very different from resumming expansions) consists in transforming the original equations (1.1) and (1.2) into fixed point equations (see (2.9) and (7.7), respectively). The main observation that allows us to solve the fixed point equations is that we are allowed to use the strong dissipation in the contraction mapping principle.

Our method also works for finitely differentiable problems. In such case, we will introduce Sobolev spaces, in which the norms of functions are measured by size of the Fourier coefficients.

We think that the regularity results obtained in this paper are close to optimal. As for the optimality for the domain, we find that there exist arbitrarily small values of $\varepsilon$ for which the map we constructed is not a contraction and the method of the proof breaks down. Therefore, we conjecture that this is optimal and that indeed, regular solutions do not exist for these small parameter values and general forcing and nonlinearity. We also show in Remark 16 that, both in the analytic and in the finitely differentiable case, there are examples in which the solution is not differentiable in $\varepsilon$ at $\varepsilon = 0$ when we remove the Diophantine condition on the forcing frequency $\omega$.

The lack of differentiability at $\varepsilon = 0$ is a reflection of the problem being a singular perturbation. In the case considered here that there are no non-resonance conditions on the frequency, the problem is more severe than in previously considered cases.

1.3. Some possible generalization. Our method could deal easily with the general case with the form of

\begin{equation}
\mathbf{p} x_{tt} + \frac{1}{\varepsilon} \mathbf{q} x_t + g(x, \omega t) = f(\omega t), \quad x \in \mathbb{R}^n,
\end{equation}

where $\mathbf{p}$, $\mathbf{q}$ are diagonal constant matrix and $g(x, \omega t) = A x + \hat{g}(x, \omega t)$, where $A$ is a matrix in Jordan Block form and $\hat{g}(x, \omega t) : \mathbb{R}^n \times \mathbb{T}^d \to \mathbb{R}^n$ is sufficiently regular. We leave the easy details to the interested readers. See Remark 13, which gives some simplified calculations after we have carried out the case in (1.1).

1.4. Organization of this paper. Our paper is organized as follows: In Section 2, we present the idea of reformulating the existence of response solutions for equation (1.1) as a fixed point problem. To solve this fixed point equation, in Section 3, we give the precise function spaces that we work in and we list their important properties, such as Banach algebra properties and the regularity of the composition operators. We state our three main results: analytic case, highly differentiable case and low regularity in Section 4. Section 5 is mainly devoted to the proof of our analytic result by contraction mapping principle. In the process, we need to pay more attention to the invertibility of operators and regularity of composition operators. In Section 6, we prove our regular result in the finitely differentiable case by the contraction argument and the implicit function theorem. Section 7 is an application to the ill-posed PDE (1.2) by a similar idea to used for ODE (1.1).
2. The formulation for equation (1.1)

In this section, we give an overview of our treatment for ODE model (1.1), which can be rewritten as

\[ \varepsilon x_{tt} + x_t + \varepsilon g(x) = \varepsilon f(\omega t), \quad x \in \mathbb{R}^n, \]  

where, as indicated before, the mappings \( g : \mathbb{R}^n \to \mathbb{R}^n, \ f : \mathbb{T}^d \to \mathbb{R}^n \). We will reduce the existence of response solutions of equation (2.1) to an equivalent fixed point problem. To this end, it is crucial to make some assumptions for equation (2.1).

2.1. Preliminaries. For the analytic and highly differentiable functions \( f \) and \( g \) defining the equation (2.1), we assume that:

\( H \): The average of \( f \) is 0 and \( g(0) = 0 \). Denote \( A = Dg(0) \), which is a \( n \times n \) matrix, the spectrum \( \lambda_j (j = 1, \cdots, n) \) of \( A \) is real and \( \lambda_j \neq 0 \).

Actually, we could weaken the assumptions on the regularity of the function \( g \) when considering low regularity results (e.g., \( L^2 \) or \( H^1 \)). As we will see in Section 6.2, instead of assuming \( g \) is differentiable, we just assume that:

\( \tilde{H} \): \( g \) is Lipschitz in \( \mathbb{R}^n \) and it can be expressed in the form of

\[ g(x) = Ax + \hat{g}(x), \]

where \( A \) is a \( n \times n \) matrix and its spectrum is real and nonzero. Moreover, the nonlinear part \( \hat{g} \) satisfies that \( \text{Lip}(\hat{g}) \ll 1 \) in the whole of \( \mathbb{R}^n \).

Note that in both assumptions \( H \) and \( \tilde{H} \), we are not including that the matrix \( A \) is diagonalizable. Non-diagonalizable matrices appear naturally when considering oscillators at resonance, which is often a design goal in several applications in electronics or appear in mechanical systems with several nodes.

We emphasize that the assumption \( \tilde{H} \) involves assumptions on \( \hat{g} \) for all values of its argument. This is needed when we consider solutions in \( L^2(\mathbb{T}^d) \) which may be unbounded.

It is important to note that, once we have established the conclusion for \( g \) under the assumption \( \tilde{H} \), we can accommodate several physical situations such as piecewise linear nonlinearity with small breaks.

Without loss of generality, we assume that

\[ \omega \cdot k \neq 0, \ \forall k \in \mathbb{Z}^d \setminus \{0\}. \]  

Indeed, if there is \( k_0 \in \mathbb{Z}^d \setminus \{0\} \) such that \( \omega \cdot k_0 = 0 \), we could reformulate the forcing with only \((d-1)\)-dimensional variables which are orthogonal to \( k_0 \). Namely, the map \( f : \mathbb{T}^{d-1} \to \mathbb{R}^n \).

The condition (2.2) is called the “non-resonance” condition. If the non-resonance condition (2.2) is satisfied, the set \( \{\omega t\}_{t \in \mathbb{R}} \) is dense on \( \mathbb{T}^d \).

2.2. Quasi-periodic solutions, hull functions. In this paper, we are interested in finding the quasi-periodic solutions with frequency \( \omega \in \mathbb{R}^d \). These are functions of time \( t \) with the form

\[ x_\varepsilon(t) = U_\varepsilon(\omega t) \]

for a suitable function \( U_\varepsilon : \mathbb{T}^d \to \mathbb{R}^n \), indexed by the small parameter \( \varepsilon \). The function \( U_\varepsilon \) is often called the “hull function”. Substituting (2.3) into equation (2.1)
and using that \( \{ \omega \} \in \mathbb{R}^d \) is dense in \( \mathbb{T}^d \), we obtain that (2.1) holds for a continuous function \( U_\varepsilon \) if and only if the hull function \( U_\varepsilon \) satisfies
\[
\varepsilon (\omega \cdot \partial_\theta)^2 U_\varepsilon (\theta) + (\omega \cdot \partial_\theta) U_\varepsilon (\theta) + \varepsilon g(U_\varepsilon (\theta)) = \varepsilon f(\theta).
\]
Hence, our treatment for equation (2.1) will be based on finding \( U_\varepsilon \) which solves (2.4). We will manipulate (2.4) to reformulate it as a fixed point problem that can be solved by the contraction argument (or the implicit function theorem).

The equation (2.4) we will solve involves parameter \( \varepsilon \) (the inverse of coefficient multiplying the damping). We will obtain solutions with delicate regularity in \( \varepsilon \), which are objects in a space of functions. Precisely, in the analytic case (see Section 5), we will get a solution \( U_\varepsilon \) of equation (2.4) depending analytically on \( \varepsilon \) when \( \varepsilon \) ranges on a complex domain \( \Omega \) which does not include the origin \( \varepsilon = 0 \) but so that the origin is in the closure of \( \Omega \). In the finitely differentiable case (see Section 6), the solution \( U_\varepsilon \) is differentiable in \( \varepsilon \) when \( \varepsilon \) is in a real domain \( \tilde{\Omega} \) which does also not include zero but includes it in its closure.

However, when we consider the regularity for the solution \( U_\varepsilon \) of equation (2.4) as \( \varepsilon \) goes to 0, we get that \( U_\varepsilon \) is continuous in \( \varepsilon \) in the topologies used in the fixed point problem (see Lemma (17)). Moreover, we will show that, in the generality considered in this paper, there are cases in which the solution is not differentiable at \( \varepsilon = 0 \) (see Remark 16).

Later, we will develop analogous procedures for the PDE model (1.2) (see Section 7). We anticipate that the treatment is inspired by this section presenting the formulation for ODE. The unknowns will not take values in \( \mathbb{R}^n \), but rather will take values in a Banach space of functions. In addition, the partial differential equation (1.2) is ill-posed and its nonlinearity is unbound, which make us do some more drastic rearrangement for its fixed point equation (see (7.4)).

### 2.3. Formulation of the fixed point problem

In this part, we just present the formal manipulations. The precise set up will follow, but it is natural to present first the formal manipulations since the rigorous setting is chosen to make them precise.

Our goal is to transform equation (2.4) into an equivalent fixed point problem. We rewrite (2.4) as
\[
\varepsilon (\omega \cdot \partial_\theta)^2 U_\varepsilon (\theta) + (\omega \cdot \partial_\theta) U_\varepsilon (\theta) + \varepsilon AU_\varepsilon (\theta) = \varepsilon f(\theta) - \varepsilon \hat{g}(U_\varepsilon (\theta)),
\]
where \( A \) is a constant matrix and
\[
\hat{g}(x) = g(x) - Ax.
\]

Note that, in both the analytic case and the highly differentiable case, we use assumption \( \mathbf{H} \). It is obvious that
\[
\hat{g}(0) = 0, \ D\hat{g}(0) = 0.
\]
Namely,
\[
\hat{g}(x) = O(x^2), \ D\hat{g}(x) = O(x),
\]
where \( O(x) \) denotes the same order as \( x \). As a consequence, \( D\hat{g} \) is small (in many sense) in a small neighborhood of the origin \( x = 0 \). We could also assume that \( D\hat{g} \) is globally small. This is trivial in the sense of complex analyticity by Liouville’s theorem. When \( g \) is just Lipschitz, we need that \( \text{Lip}(\hat{g}) \) is globally small as condition \( \tilde{\mathbf{H}} \).
Based on equation (2.5) and denoting by $Id$ the $n \times n$ identity matrix, we introduce the linear operator $\mathcal{L}_\varepsilon$ as

\begin{equation}
\mathcal{L}_\varepsilon = \varepsilon (\omega \cdot \partial \theta)^2 Id + (\omega \cdot \partial \theta) Id + \varepsilon A,
\end{equation}

defined on $n$-dimensional periodic functions of $\theta \in \mathbb{T}^d$. Then, (2.5) can be rewritten by

\begin{equation}
\mathcal{L}_\varepsilon(U_\varepsilon(\theta)) = \varepsilon f(\theta) - \varepsilon \hat{g}(U_\varepsilon(\theta)).
\end{equation}

As shown in Section 5.1, the operator $\mathcal{L}_\varepsilon$ is boundedly invertible in the space $H^{p,m}$ defined in Section 3 when $\varepsilon$ ranges in a suitable complex domain. This allows the equation (2.8) to be transformed into a fixed point problem as

\begin{equation}
U_\varepsilon(\theta) = \varepsilon \mathcal{L}_\varepsilon^{-1}[f(\theta) - \hat{g}(U_\varepsilon(\theta))] = \mathcal{T}_\varepsilon(U_\varepsilon(\theta)),
\end{equation}

where we have introduced the operator $\mathcal{T}_\varepsilon$. For a fixed $\varepsilon$, we can obtain a solution $U_\varepsilon$ for equation (2.9) by the contraction mapping principle. Further, we want to get a solution $U_\varepsilon$ possessing optimal regularity in $\varepsilon$. This can be achieved by considering operator $\mathcal{T}$ above in a function space consisting of functions regular in $\varepsilon$ (see Section 5.2 for analytic case and Section 6.1.1 for highly differentiable case). Specially, in the highly differentiable case, we will use the classic implicit function theorem to get the results with optimal regularity in $\varepsilon$. For convenience, we now introduce the operator $\mathcal{T}$ involving the arguments $\varepsilon$ and $U$ as the following:

\begin{equation}
\mathcal{T}(\varepsilon, U) := U - \mathcal{T}(\varepsilon, U).
\end{equation}

This makes it clear to obtain the solution $U = U_\varepsilon$, as a function of $\varepsilon$, having the same regularity as $\mathcal{T}$ by the classical implicit function theorem.

Two subtle points appear in this strategy. One is the invertibility of the linear operator $\mathcal{L}_\varepsilon$ and the bound of its inverse. Another is the regularity of the composition operator $\hat{g} \circ U$ in (2.9). We also need to study the dependence on the parameter $\varepsilon$ of the solution $U_\varepsilon$ satisfying equation (2.9).

We observe that the linear operator $\mathcal{L}_\varepsilon$ is diagonal in the basis of Fourier functions. This suggests that we use some variants of Sobolev (or Bergman) spaces which provide analyticity – or in the low regularity case $L^2$ or $H^1$. Hence, it will be useful that the spaces we consider have norms that can be estimated very easily by estimating the Fourier coefficients. The estimates of the Fourier coefficients involves the assumptions that the eigenvalues of $A$ are nonzero real number and that the range of $\varepsilon$ is restricted to a domain accumulating at the origin $\varepsilon = 0$. (See Section 5.1.2 for details).

For the nonlinear estimates, we need that the composition operator defined by $\hat{g} \circ U$ is smooth considered as a mapping acting on the spaces we consider. The regularity of the composition on the left by a smooth functions acting on variants of Sobolev spaces have been widely studied [Mar74, AZ90, IKT13]. In Sections 3, we will present the precise spaces and some properties in these spaces used to implement our program.

2.4. Some heuristic considerations on the smallness conditions required for the present method. Recall the fixed point equation (2.9), the operator we consider has the structure

\begin{equation}
U = \varepsilon \mathcal{L}_\varepsilon^{-1} f - \varepsilon \mathcal{L}_\varepsilon^{-1} \hat{g}(U) \equiv \mathcal{T}_\varepsilon(U).
\end{equation}
To solve it by iteration, roughly, we need that the map $U \rightarrow \varepsilon \mathcal{L}_\varepsilon^{-1} \hat{g} \circ U$ is a contraction in a domain that contains a ball around $\varepsilon \mathcal{L}_\varepsilon^{-1} f$. Of course, the notions of contraction and smallness depend on the spaces under consideration. The results of existence are sharper if we consider spaces of more regular functions and the results of local uniqueness are sharper if we consider spaces of less regular functions.

Both the contraction properties of $\varepsilon \mathcal{L}_\varepsilon^{-1} \hat{g} \circ U$ and the smallness properties of $\varepsilon \mathcal{L}_\varepsilon^{-1} f$ are formulated in appropriate norms (which change with the regularity considered). As we will see in Section 5.1, the operator $\varepsilon \mathcal{L}_\varepsilon^{-1}$ can be bounded in appropriate norms, which allows us to just consider the smallness of $f$ and the properties of the composition $\hat{g} \circ U$.

To this end, it is clear that we can trade off some of the smallness assumptions in $\hat{g}$ and $f$. If we are willing to make global assumptions of smallness on $\hat{g}$, we do not need any smallness assumption on $f$. If, on the other hand, we assume that $\hat{g}$ is smooth and $\hat{g}(0) = D\hat{g}(0) = 0$, we have that $\hat{g}$ is small (in many senses) in a small neighborhood at the origin. From this point of view, it is necessary to impose smallness condition on $f$ in this small neighborhood.

There are some caveats to these arguments:

In the analytic case, assuming that $D\hat{g}$ is small globally (even bounded) in the whole complex space $\mathbb{C}^n$, Liouville’s theorem shows that it is constant, namely, $\hat{g}$ is linear. This makes our result true, but it is trivial and we will not state it. Of course, Liouville’s theorem is only a concern for analytic results.

In the low regularity cases (e.g. $L^2$ or $H^1$ when $d \geq 2$), the range of $f$ may be the whole of $\mathbb{R}^n$, hence we need to make global assumptions on smallness in $\hat{g}$. In the case of $H^m$ regularity with $m > \frac{d}{2}$, we prove our results under two types of smallness assumptions (See Section 6.1).

We also advance that in the case of $H^1$ regularity, the contraction argument we use will be somewhat more sophisticated. (See Section 6.2).

3. Function spaces

3.1. Choice of spaces. To implement the fixed point problem outlined in Section 2, we need to define precisely function spaces with appropriate norms. The discussion in Section 5 will make clear, it is very convenient that the norms can be expressed in terms of the Fourier coefficients of functions. In such a case, the inverse of the linear operator $\mathcal{L}_\varepsilon$ can be easily estimated just by estimating its Fourier coefficients. We are allowed to use the base in a such way that the Fourier coefficients of the multiplier operator $\mathcal{L}_\varepsilon$ have the Jordan standard form. (See Section 5.1.1).

We also need the spaces to possess other properties allowing us to control the composition $\hat{g} \circ U$ in (2.9) with ease, such as Banach algebras properties under multiplication and the properties of the composition operators. To study the analyticity in $\varepsilon$, we will define spaces of analytic functions of $\varepsilon$ in Section 5.2. In this section, we use the same notations for Banach spaces as in [dlL09, CCdlL13, dlLS19].

For $\rho \geq 0$, we denote

$$T^d_\rho = \{ \theta \in \mathbb{C}^d/(2\pi\mathbb{Z})^d : \text{Re}(\theta_j) \in \mathbb{T}, |\text{Im}(\theta_j)| \leq \rho, j = 1, \ldots, d \}.$$

We denote the Fourier expansion of a periodic function $f(\theta)$ on $T^d_\rho$ by

$$f(\theta) = \sum_{k \in \mathbb{Z}^d} \hat{f}_k e^{i k \cdot \theta},$$

where $f(\theta)$ is a periodic function on $\mathbb{T}^d$.
where $k \cdot \theta = k_1 \theta_1 + \cdots + k_d \theta_d$ represents the Euclidean product in $\mathbb{C}^d$ and $\hat{f}_k$ are the Fourier coefficients of $f$. If $f$ is analytic and bounded on $\mathbb{T}_d^d$, then the Fourier coefficients satisfy the Cauchy bounds

$$|\hat{f}_k| \leq Me^{-|k|\rho}$$

with $M$ being the maximum of $|f(\theta)|$ on $\mathbb{T}_d^d$ and $|k| = |k_1| + \cdots + |k_d|$.

**Definition 1.** For $\rho \geq 0$, $m$, $d$, $n \in \mathbb{N}_+$, we denote by $H^{\rho,m}$ the space of analytic functions $U$ in $\mathbb{T}_d^d$ with finite norm:

$$H^{\rho,m} := H^{\rho,m}(\mathbb{T}_d^d) = \left\{ U : \mathbb{T}_d^d \to \mathbb{C}^n \mid \|U\|_{\rho,m}^2 = \sum_{k \in \mathbb{Z}_d^d} |\hat{U}_k|^2 e^{2\rho|k|} (|k|^2 + 1)^m < +\infty \right\}.$$  

It is obvious that the space $(H^{\rho,m}, \| \cdot \|_{\rho,m})$ is a Banach space and indeed a Hilbert space. From the real analytic point of view, we consider the Banach space $H^{\rho,m}$ of the functions that take real values for real arguments.

For $\rho = 0$, $H^m(\mathbb{T}_d^d) := H^0,m(\mathbb{T}_d^d)$ is the standard Sobolev space, we refer to the references [Tay97, AF03] for more details. In this case, when $m > \frac{d}{2}$, by the Sobolev embedding theorem (see chapter 2 and 6 in [Tay97]), we obtain that $H^{m+l}(\mathbb{T}_d^d) (l = 1, 2, \cdots)$ embeds continuously into $C^l(\mathbb{T}_d^d)$.

For $\rho > 0$, functions in the space $H^{\rho,m}$ are analytic in the interior of $\mathbb{T}_d^d$ and extend to Sobolev functions on the boundary of $\mathbb{T}_d^d$.

**Remark 2.** As a matter of fact, when $\rho > 0$ and $m > d$, the space $H^{\rho,m}$ can be identified with a closed space of the standard Sobolev space $H^m(\mathbb{T}_d^d)$ consisting of functions which are complex differentiable. The manifold $\mathbb{T}_d^d$ has $2d$ real dimension so that, when $m > d$, the standard Sobolev embedding theorem shows that $H^{\rho,m+1} (l = 1, 2, \cdots)$ embeds continuously into $C^l(\mathbb{T}_d^d)$. Since the uniform limit of complex differentiable functions is also complex differentiable, we conclude that our space is a closed space of the standard Sobolev space of $\mathbb{T}_d^d$ considered as a $2d$–dimensional real manifold. Several variants of this idea appear already in Bergman spaces in [RS75, RS80].

We also point out that the set of functions in $H^{\rho,m}$ which take real values for real arguments is a closed set in $H^{\rho,m}$ (this set is also a linear space over the reals). Since we will show that our operators map this set into itself, we get that the fixed point we produce will be such that they give real values for real arguments.

### 3.2. Properties of the chosen spaces $H^{\rho,m}$ above

We note several well-known properties of the space $H^{\rho,m}$ defined in the Section 3.1, which will play a crucial role in what follows.

**Lemma 3.** (Interpolation inequalities) For any $0 \leq i \leq m$, $0 \leq \nu \leq 1$, denote $s = (1 - \nu)i + \nu m$, there exist constants $C_{i,m}$ depending on $i, m$ such that

1. -Sobolev case: for $f \in H^m$, we have that

$$\|f\|_{H^s} \leq C_{i,m} \cdot \|f\|_{H^m}^{1-\nu} \cdot \|f\|_{H^m}^\nu.$$

2. -Analytic case: for $\rho > 0$, $g \in H^{\rho,m}$, we have that

$$\|g\|_{H^{\rho,s}} \leq C_{i,m} \cdot \|g\|_{H^{\rho,m}}^{1-\nu} \cdot \|g\|_{H^{\rho,m}}^\nu.$$
The inequality (3.1) is the very standard Sobolev interpolation inequality in the literature [Tay97, Zeh75]. Since, as mentioned before, the spaces $H^{ρ,m}(T^d)$ can be considered as a subspace of the standard Sobolev space in $T^d$, we also have (3.2).

**Lemma 4.** (Banach algebra properties)

(1) Sobolev case (see [AF03, Tay97]): Let $m > \frac{d}{2}$, there exists a constant $C_{m,d}$ depending only on $m, d$ such that for $u_1, u_2 \in H^m$, the product $u_1 \cdot u_2 \in H^m$ and

$$\|u_1 u_2\|_{H^m} \leq C_{m,d} \|u_1\|_{H^m} \|u_2\|_{H^m}.$$ 

(2) Analytic case: For $ρ > m > d$, there exists a constant $C_{ρ,m,d}$ depending on $ρ, m, d$ such that for $u_1, u_2 \in H^{ρ,m}$, the product $u_1 \cdot u_2 \in H^{ρ,m}$ and

$$\|u_1 u_2\|_{H^{ρ,m}} \leq C_{ρ,m,d} \|u_1\|_{H^{ρ,m}} \|u_2\|_{H^{ρ,m}}.$$ 

In particular, $H^{ρ,m}$ is a Banach algebra when $ρ, m, d$ are as above.

To analyze the operator defined in (2.9), we also need to estimate the properties of the composition operator $\hat{g} \circ U$. The following are well known consequence of Gagliardo-Nirenberg inequalities.

**Lemma 5.** (Composition properties)

(1) Sobolev case (see [Tay97, CdlL10]): Let $g \in C^m(\mathbb{R}^n, \mathbb{R}^n)$ and assume that $g(0) = 0$. Then, for $u \in H^m(T^d, \mathbb{R}^n) \cap L^∞(T^d, \mathbb{R}^n)$, we have

$$\|g(u)\|_{H^m} \leq c \|u\|_{L^{∞}} (1 + \|u\|_{H^m}),$$

where $c := c(\eta) = \sup_{|x| \leq R, \alpha \leq m} |D^α g(x)|$. Particularly, when $m > \frac{d}{2}$ (so that, by the Sobolev embedding theorem $H^m \subset L^{∞}$), if $g \in C^{m+2}$, then

$$\|g(u + v) - g \circ u - Dg \circ u \cdot v\|_{H^m} \leq C_{m,d} \|u\|_{L^{∞}} (1 + \|u\|_{H^m}) \|g\|_{C^{m+2}} \|v\|_{H^m}^2.$$ 

(2) Analytic case: Let $g : B \to C^n$ with $B$ being an open ball around the origin in $C^n$ and assume that $g$ is analytic in $B$. Then, for $u \in H^{ρ,m}(T^d, C^n) \cap L^∞(T^d, C^n)$ with $u(T^d) \subset B$, we have

$$\|g(u)\|_{H^{ρ,m}} \leq C_u \|u\|_{L^{∞}(T^d)} (1 + \|u\|_{H^{ρ,m}}),$$

where $C_u$ is a constant depending on the norm of $u$. In the case of $m > d$, we have that

$$\|g \circ (u + v) - g \circ u - Dg \circ u \cdot v\|_{H^{ρ,m}} \leq C_{ρ,m,d} \|u\|_{L^{∞}(T^d)} (1 + \|u\|_{H^{ρ,m}}) \|v\|_{H^{ρ,m}}^2.$$ 

The complete proof of Lemma 5 can be found in Proposition 3.9 in [Tay97] or Proposition 2.20 in [IKT13]. Proposition 1 in [Mar74]. To make the paper self-contained, we just give an sketch of the ideas for the inequality (3.3), but refer the interested readers to the references above.

Since

$$g \circ (u + v)(θ) - g \circ u(θ) - Dg \circ u(θ) \cdot v(θ) = \int_0^1 \int_0^t D^2 g \circ (u + tsv)(θ) \cdot v^2(θ) ds dt,$$

we get the desired result by the facts that $D^2 g \circ (u + tsv) \in H^m$ and its $H^m$ norm is bounded uniformly in $t, s$ and that $H^m$ is a Banach algebra under multiplication by Lemma 4. The range of the derivative $Dg$ is a $n \times n$ matrix, which can be identified
with $\mathbb{R}^n$. Note that the dimension of the range of $g$ does not play any role in our arguments.

The proof of Lemma 5 is rather elementary in the analytic case.

As a matter of fact, Lemma 5 gives not only the composition operator is differentiable but also presents formula for the derivative. It is easy to check that the same argument leads to higher derivatives of the composition operator if we assume more regularity for function $g$. More precisely, we have the following proposition:

**Proposition 6.** (Regularity of composition operators)

(1) - Sobolev case: Let $m > \frac{d}{2}$. Then, the left composition operator

$$C_g : H^m(T^d, \mathbb{R}^n) \to H^m(T^d, \mathbb{R}^n)$$

defined by

$$C_g[u](\theta) = g(u(\theta)),$$

has the following properties:

If $g \in C^{m+1}(\mathbb{R}^n, \mathbb{R}^n)$, then $C_g$ is Lipschitz.

If $g \in C^{m+l+1}(\mathbb{R}^n, \mathbb{R}^n)$, $(l = 1, 2, \cdots)$, then $C_g$ is $C^l$. Moreover, the derivative of the operator $C_g$ is given by

$$(DC_g[u]v)(\theta) = Dg(u)v(\theta).$$

(2) - Analytic case: Let $\rho > 0$. Assume that $m > d$ and $g : B \to \mathbb{C}^n$, where $B$ is an open ball around the origin in $\mathbb{C}^n$, is analytic in $B$.

Let $u_0 \in H^{p,m}$ be such that $u_0(T^d_\rho) \subset B$. Then for all $u$ in a neighborhood $U$ of $u_0$ in $H^{p,m}$, the operator $C_g : U \to H^{p,m}$ is analytic. Moreover, for $v \in H^{p,m}$, the derivative of the operator $C_g$ is given by

$$(DC_g[u]v)(\theta) = Dg(u)v(\theta).$$

**Proof.** In fact, Lemma 5 shows that the operator $C_g$ is $C^1$ when $g \in C^{m+2}$. For $g \in C^{m+l+1}$, we can proceed by induction. If we have proved the result for $l$ and the formula for the derivative, we obtain the case for $l+1$. Indeed, if $g \in C^{m+l+1}$, we have $C_g$ is $C^l$. Then, for $g \in C^{m+l+2}$, $Dg \in C^{m+l+1}$, we get $DC_g$ is $C^l$ by induction. Namely, $C_g$ is $C^{l+1}$.

In the analytic case, we start by observing that $u(T^d_\rho) \subset B$ is a compact set by the Sobolev embedding theorem. Hence, it is at a bounded distance from the boundary of $B$. If the neighborhood of $u$ is sufficiently small, the range of all the functions will also be contained in $B$. Then, we obtain our result by Lemma 5. We can also refer to [CCCdlL17] for more details. 

Note that, for the Sobolev case in Proposition 6, the regularity of $C_g$ is not optimal, we refer to [RS96, AZ90, IKT13] for more results. Note also that, for the analytic case in Proposition 6, the result is not the most general result. There are results in the case of regularity that the Sobolev embedding theorem does not give continuity. In these cases, we need to take more care of the ranges of the functions. Since the functions are differentiable in the complex sense, we obtain that the composition operator $C_g$ is differentiable in the complex sense by the chain rule to obtain the derivative. Further, to get that the operator $C_g$ is analytic, we just recall the Cauchy result that also holds for functions whose arguments range over a complex Banach space. See [HP74].
4. Statement of the main results

In this section, we state several results for the model (2.1). These results are
directed at different regularity of the forcing \( f \): analyticity (Theorem 7), finite (but
high enough) number of derivatives (Theorem 9) and low regularity (Theorem 10).

**Theorem 7.** Suppose that \( f \in H^{\rho,m}(\mathbb{T}^d) \) for some \( \rho > 0 \), \( m > d \) and \( g \) is analytic
in an open ball around the origin in the space \( \mathbb{C}^n \). If the condition \( \mathbf{H} \) is satisfied,
then, for \( \varepsilon \in \Omega(\sigma, \mu) \), where

\[
\Omega := \Omega(\sigma, \mu) = \{ \varepsilon \in \mathbb{C} : \Re(\varepsilon) \geq \mu |\Im(\varepsilon)|, \sigma \leq |\varepsilon| \leq 2\sigma \}
\]

with \( \mu > \mu_0 \) for \( \mu_0 > 0 \) sufficiently large and \( \sigma > 0 \) sufficiently small, there is a
unique solution \( U_\varepsilon \in H^{\rho,m}(\mathbb{T}^d) \) for equation (2.4).

Furthermore, considering \( U_\varepsilon \) as a function of \( \varepsilon \), the mapping \( \varepsilon \rightarrow U_\varepsilon : \Omega \rightarrow H^{\rho,m}(\mathbb{T}^d) \) is analytic when \( m > (d+2) \).

In addition, as \( \varepsilon \rightarrow 0 \), the solution \( U_\varepsilon \rightarrow 0 \) and the mapping \( \varepsilon \rightarrow U_\varepsilon \) is continuous.

**Remark 8.** The statement of Theorem 7 does not impose any Diophantine condition on the forcing frequency \( \omega \). Since we do not expand the solution as a power
series in \( \varepsilon \), there is no equation involving the small divisor appearing. We will,
however, not get that the solution is differentiable with respect to \( \varepsilon \) at the origin
\( \varepsilon = 0 \) and this may indeed be false in the generality considered in this paper. (See
Remark 16).

**Theorem 9.** Suppose that \( f \in H^m(\mathbb{T}^d) \) with \( m > \frac{d}{2} \) and \( g \in C^{m+l}(\mathbb{R}^n, \mathbb{R}^n) \) \((l =
1, 2, \cdots)\). If the condition \( \mathbf{H} \) is satisfied, then, for \( \varepsilon \in \Omega(\sigma) \), where

\[
\tilde{\Omega} := \tilde{\Omega}(\sigma) = \{ \varepsilon \in \mathbb{R} : \sigma \leq |\varepsilon| \leq 2\sigma \}
\]

with sufficiently small \( \sigma > 0 \), there exists a unique solution \( U_\varepsilon \in H^m(\mathbb{T}^d) \) for equation (2.4).

Moreover, we have the following regularity in \( \varepsilon \):
If \( g \in C^{m+l}(\mathbb{R}^n, \mathbb{R}^n) \), then the mapping \( \varepsilon \rightarrow U_\varepsilon : \Omega \rightarrow H^m(\mathbb{T}^d) \) is Lipschitz.
If \( g \in C^{m+l+1}(\mathbb{R}^n, \mathbb{R}^n) \), then the mapping \( \varepsilon \rightarrow U_\varepsilon : \tilde{\Omega} \rightarrow H^m(\mathbb{T}^d) \) is \( C^l \).

In addition, when \( \varepsilon \rightarrow 0 \), the solution \( U_\varepsilon \rightarrow 0 \) and \( \varepsilon \rightarrow U_\varepsilon \) is continuous.

We note that the regularity in \( \varepsilon \) in Theorem 9 depends on the regularity of the
composition operator \( g \circ u \) in Proposition 6. Even if we show that the derivatives
with respect to \( \varepsilon \) exist for all \( \varepsilon > 0 \), we do not make any claim about the limit of the
derivatives as \( \varepsilon \) goes to 0.

The following Theorem 10 is for the situation when the forcing and the nonlin-
earity are rather irregular.

**Theorem 10.** Suppose that \( f \in L^2(\mathbb{T}^d) \) and \( g \) is globally Lipschitz continuous on
\( \mathbb{R}^n \) satisfying the condition \( \tilde{\mathbf{H}} \). Then, for \( \varepsilon \in \tilde{\Omega} \subset \mathbb{R} \setminus \{0\} \) being the sufficiently small
domain, there is a unique solution \( U_\varepsilon \in L^2(\mathbb{T}^d) \) for equation (2.4). The solution
\( U_\varepsilon \) is continuous in \( \varepsilon \).

Under the above assumptions if \( f \in H^1(\mathbb{T}^d) \) and \( g \in C^{1+Lip} \), then, the unique
solution \( U_\varepsilon \) constructed above is in \( \cap_{0 \leq s \leq 1} H^s \).
Note that Theorem 10 applies to some piecewise linear models (the Lipschitz constant of the derivatives has to be sufficiently small). Such models appear naturally in many areas.

We also stress that in Theorem 10, for \( f \in H^1(T^d) \), we cannot claim that the solution is in \( H^1 \), but only that it belongs to the intersection \( \cap_{0 \leq s < 1} H^s \). We do not have a contraction argument in this case, but we can estimate the speed of convergence of the iterative procedure in the space \( H^s \) for \( 0 \leq s < 1 \).

In the analytic case (Theorem 7) and in the highly differentiable regularity (Theorem 9), when \( m > (d^2 + 2) \), we have that the solution \( U_\varepsilon \) is \( C^2 \) with respect to the argument \( \theta \). Hence, the quasi-periodic solutions \( x(t) \) obtained through (2.3) is also a twice differentiable function of time. As a consequence, the solutions we have produced satisfy the differential equation (1.1) in the classical sense. In the lower regularity case, the solutions we produce solve the equation in the sense that the Fourier coefficients of (2.4) are the same in both sides. This is equivalent to solving (1.1) in the weak sense since the trigonometric polynomials are dense in the space of \( C^\infty \) test functions.

In this paper, we also present some results for PDE's model (1.2). Since the formulation requires new definitions and auxiliary lemmas, we postpone the formulation of the results till Section 7.

5. Analytic case: Proof of Theorem 7

We prove Theorem 7 in the analytic sense by considering the fixed point equation (2.9) in the Banach space \( H^{\rho,m} \) for any \( \varepsilon \in \Omega(\sigma,\mu) \). Recall the equation (2.9)

\[
U_\varepsilon(\theta) = \mathcal{L}_\varepsilon^{-1} [\varepsilon f(\theta) - \varepsilon \hat{g}(U_\varepsilon(\theta))] \equiv \mathcal{T}_\varepsilon(U_\varepsilon)(\theta).
\]

The first concern is the invertibility of the linear operator \( \mathcal{L}_\varepsilon \) and the quantitative bounds on its inverse when \( \varepsilon \) ranges over the complex domain \( \Omega(\sigma,\mu) \) defined in (4.1). We remark that it is impossible to obtain the same bounds if \( \varepsilon \) belongs to the imaginary axis. In fact, we conjecture that the optimal domain of \( \varepsilon \), when the solution \( U_\varepsilon \) of equation (5.1) is considered as a function of \( \varepsilon \), do not extend to the imaginary axis.

Secondly, since we want to obtain a solution \( U_\varepsilon \) analytic in \( \varepsilon \), we will define a space consisting of functions analytic in \( \varepsilon \). (See the space \( H^{\rho,m,\Omega} \) defined in Section 5.2). By reinterpreting the fixed point problem in the space \( H^{\rho,m,\Omega} \), we obtain rather directly the analytic dependence on \( \varepsilon \) of the solutions \( U_\varepsilon \). The delicate steps are to show that the operator \( \mathcal{T} \) defined in (5.1) maps a ball centered at the origin in the space \( H^{\rho,m,\Omega} \) to itself and it is a contraction in this ball.

5.1. Estimates on the inverse operator \( \mathcal{L}_\varepsilon^{-1} \). For the analytic nonlinearity \( g \), the linear part \( A \) is dominant with respect to the nonlinear part \( \hat{g} \). Moreover, the Lipschitz constant of \( \hat{g} \) can be small enough in a sufficiently small domain.

We now study the linear operator defined by

\[
\mathcal{L}_\varepsilon = \varepsilon (\omega \cdot \partial_\theta)^2 Id + (\omega \cdot \partial_\theta) Id + \varepsilon A.
\]

Our main result in this section includes that \( \mathcal{L}_\varepsilon \) is boundedly invertible from the analytic function space \( H^{\rho,m} \) to itself when \( \varepsilon \) ranges over a complex conical domain \( \Omega(\sigma,\mu) \), which is away from imaginary axis. Of course, this result requires the assumptions on \( A \) in \( \mathcal{H} \).
A key ingredient for the result is that the norms of the functions can be read off from the sizes of the Fourier series and that the operator $L_\varepsilon$ acts in a very simple matter in Fourier series. Indeed, if the matrix $A$ was diagonal, the operator $L_\varepsilon$ will be just a Fourier multiplier in each component (this case is worth keeping in mind as a heuristic guide).

5.1.1. Some elementary manipulations. A consequence of the assumption $H$ is that there exists a basis of generalized eigenvectors $\Phi_i \in \mathbb{C}^n \ (i = 1, 2, \cdots, n)$ such that

$$A\Phi = J\Phi, \ \Phi = (\Phi_1, \cdots, \Phi_n)^T, \tag{5.2}$$

where $J$ is the standard Jordan normal form. That is,

$$J = \begin{pmatrix} J_1 & 0 & \cdots & 0 \\ J_2 & J_1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & J_1 & J_p \end{pmatrix}, \ J_j = \begin{pmatrix} \lambda_j & 0 & \cdots & 0 \\ 1 & \lambda_j & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 1 & \lambda_j \end{pmatrix}, \ 1 \leq j \leq p, 1 \leq p \leq n. \tag{5.3}$$

When we write a function $U_\varepsilon(\theta) \in H^{p,m}$ in the Fourier expansion as

$$U_\varepsilon(\theta) = \sum_{k \in \mathbb{Z}^d} \widehat{U}_{k, \varepsilon} e^{ik \cdot \theta} = \sum_{k \in \mathbb{Z}^d} \tilde{\widehat{U}}_{k, \varepsilon} \Phi e^{ik \cdot \theta},$$

with $\widehat{U}_{k, \varepsilon}, \tilde{\widehat{U}}_{k, \varepsilon} \in \mathbb{C}^n$ and $\Phi$ being in (5.2), the operator $L_\varepsilon$ acting on the Fourier basis becomes

$$L_\varepsilon(\Phi e^{ik \cdot \theta}) = (-\varepsilon (k \cdot \omega)^2 I d + i(k \cdot \omega) Id + \varepsilon J) \Phi e^{ik \cdot \theta} =: L_\varepsilon(k \cdot \omega) \Phi e^{ik \cdot \theta},$$

where

$$L_\varepsilon(a) = -\varepsilon a^2 I d + i a I d + \varepsilon J \tag{5.3}$$

with

$$L_\varepsilon(a) = \begin{pmatrix} L_{\varepsilon,1}(a) & 0 \\ L_{\varepsilon,2}(a) & \ddots \\ 0 & \ddots & L_{\varepsilon,p}(a) \end{pmatrix},$$

and

$$l_{\varepsilon,j}(a) = \begin{pmatrix} l_{\varepsilon,j}(a) & 0 \\ \varepsilon & l_{\varepsilon,j}(a) \\ \vdots & \ddots & \ddots \\ 0 & \cdots & \varepsilon & l_{\varepsilon,j}(a) \end{pmatrix}, \ (1 \leq j \leq p) \tag{5.4}$$

and

$$L_{\varepsilon}^{-1}(a) = \begin{pmatrix} L_{\varepsilon,1}^{-1}(a) & 0 \\ L_{\varepsilon,2}^{-1}(a) & \ddots \\ 0 & \ddots & L_{\varepsilon,p}^{-1}(a) \end{pmatrix}. \tag{5.5}$$

The formula (5.3) gives that

$$L_{\varepsilon}^{-1}(a) = \begin{pmatrix} L_{\varepsilon,1}(a) & 0 \\ L_{\varepsilon,2}(a) & \ddots \\ 0 & \ddots & L_{\varepsilon,p}(a) \end{pmatrix}.$$
with
\[(5.6)\]
\[
L^{-1}_{\varepsilon,j}(a) = \begin{pmatrix}
    l^{-1}_{\varepsilon,j}(a) & 0 & \cdots \\
    -\varepsilon l^{-1}_{\varepsilon,j}(a) & l^{-1}_{\varepsilon,j}(a) & \cdots \\
    \varepsilon^2 l^{-1}_{\varepsilon,j}(a) & -\varepsilon l^{-1}_{\varepsilon,j}(a) & l^{-1}_{\varepsilon,j}(a) \\
    \vdots & \ddots & \ddots \\
    (-1)^{n-1}\varepsilon^{n-1}l^{-1}_{\varepsilon,j}(a) & \cdots & \varepsilon^2 l^{-1}_{\varepsilon,j}(a) & -\varepsilon l^{-1}_{\varepsilon,j}(a) & l^{-1}_{\varepsilon,j}(a)
\end{pmatrix}.
\]

Consequently, to estimate the inverse of \(L_{\varepsilon}\), it suffices to estimate
\[(5.7)\]
\[
\Gamma_{\varepsilon} := \sup_{a \in \mathbb{R}} |L_{\varepsilon}^{-1}(a)| \geq \sup_{k \in \mathbb{Z}^d} |L_{\varepsilon}^{-1}(k \cdot \omega)|.
\]

In the following part, for ease of notation, we will drop the index \(j\) in \(l_{\varepsilon,j}(a)\) defined in (5.4). That means \(l_{\varepsilon}(a)\) stands for \(l_{\varepsilon,j}(a)\).

5.1.2. Estimating the Fourier coefficients \(L_{\varepsilon}^{-1}\) in (5.5) of the inverse operator \(L_{\varepsilon}^{-1}\).

For the matrix \(L_{\varepsilon}(a)\) with special form defined in (5.3), once we obtain the infimum of \(|l_{\varepsilon}(a)|\) in (5.4) for \(a \in \mathbb{R}\), we get the estimates of \(\Gamma_{\varepsilon}\) defined in (5.7). The following estimates are similar to those in [CCdlIL13], which considered only the 1–dimensional case. We now present the details for \(n–\)dimensional case.

Note that the estimates we obtain also apply to the standard Sobolev space \(H^m\), which allows to conclude very quickly the results for the finitely differentiable case presented in Section 6. We first deal with two special cases, which throw some light in the general case. Of course, from the purely logical point of view, these special cases can be omitted since they can be covered in the general discussion. We note that Case 1 with \(\varepsilon \in \mathbb{R}\) is the only case needed in the finite differentiability result. So it is worth dealing with it explicitly.

Case 1. When \(\varepsilon \in \mathbb{R}\), we have
\[
|l_{\varepsilon}(a)|^2 = |-\varepsilon a^2 + ia + \varepsilon \lambda_j|^2 = \varepsilon^2 a^4 + (1 - 2\varepsilon^2 \lambda_j)a^2 + \varepsilon^2 \lambda_j.
\]

Take \(G(v) = \varepsilon^2 v^2 + (1 - 2\varepsilon^2)v + \varepsilon^2 \lambda_j^2\) with \(v = a^2 \geq 0\). It is obvious that \(G(v) \geq G(0) = \varepsilon^2 \lambda_j^2\) since \(DG(v) = 2\varepsilon^2 v + (1 - 2\varepsilon^2 \lambda_j) > 0\) due to the smallness of \(\varepsilon\). Therefore, we have
\[(5.8)\]
\[
\inf_{a \in \mathbb{R}} |l_{\varepsilon}(a)| \geq |\varepsilon \lambda_j|.
\]

Namely,
\[
\sup_{a \in \mathbb{R}} |l_{\varepsilon}(a)|^{-1} \leq |\varepsilon \lambda_j|^{-1}.
\]

Together with (5.6), we have that
\[
\Gamma_{\varepsilon} = \sup_{a \in \mathbb{R}} |L_{\varepsilon}^{-1}(a)| \leq |\varepsilon|^{-1} C_{\lambda}
\]

for a positive constant \(C_{\lambda}\) depending on the eigenvalues \(\lambda_1, \lambda_2, \ldots, \lambda_n\).

Case 2. When \(\varepsilon\) is pure imaginary, i.e. \(\varepsilon = is\) with \(s \leq |s| \leq 2\sigma\). In this case, there exits a real root \(a\) such that \(|l_{\varepsilon}(a)| = 0\) since the discriminant \(1 + 4s^2 \lambda_j > 0\) (by the smallness of \(s\)) for \(-sa^2 + a + s\lambda_j = 0\). Hence, the operator \(L_{\varepsilon}\) is unbounded.
if the small parameter \( \varepsilon \) locates in the imaginary axis, which makes the contraction mapping principle inapplicable.

We conjecture that no solutions for the equation (2.5) exist when \( \varepsilon \) is purely imaginary because zero divisors can be considered as resonance.

To study the analyticity in \( \varepsilon \) of the function \( U_\varepsilon \) satisfying (5.1), it will be interesting to study the inverse of \( \mathcal{L}_\varepsilon \) when \( \varepsilon \) ranges over the complex domain \( \Omega(\sigma, \mu) \).

**Proposition 11.** For \( \Gamma_\varepsilon \) defined in (5.7), when \( \varepsilon \in \Omega(\sigma, \mu) \), we have

\[
\Gamma_\varepsilon \leq \sigma^{-1}C_{\lambda, \mu}
\]

with a positive constant \( C_{\lambda, \mu} \) depending on the eigenvalues \( \lambda_1, \lambda_2, \ldots, \lambda_n \) and \( \mu \).

**Proof.** Fix

\[
\varepsilon = s_1 + is_2,
\]

for \( \varepsilon \) lining on a conical domain \( \Omega(\sigma, \mu) \), we have \( s_1 \geq \mu|s_2| \), where \( \mu > \mu_0 \) with some sufficiently large positive constant \( \mu_0 \), and \( \sigma^2 \leq s_1^2 + s_2^2 \leq 4\sigma^2 \). Namely,

\[
\sqrt{1 + \frac{1}{\mu^2}} \cdot \sigma \leq s_1 \leq \sqrt{1 + \frac{1}{\mu^2}} \cdot 2\sigma.
\]

Then, one obtains that

\[
|l_\varepsilon(a)|^2 = | - \varepsilon a^2 + ia + \varepsilon \lambda_j |^2
\]

\[
= | - s_1(a^2 - \lambda_j) - i(s_2a^2 - a - s_2\lambda_j) |^2
\]

\[
= s_1^2(a^2 - \lambda_j)^2 + [s_2(a^2 - \lambda_j) - a]^2.
\]

If \( \lambda_j < 0 \), it is obvious that

\[
|l_\varepsilon(a)|^2 \geq s_1^2(a^2 - \lambda_j)^2 \geq s_1^2\lambda_j^2.
\]

The remaining task is to estimate \( |l_\varepsilon(a)|^2 \) in the case of \( \lambda_j > 0 \). Since \( a^2 - \lambda_j = 0 \) holds at the point \( a = \pm \sqrt{\lambda_j} \), we divide the domain of \( a \) into two parts, for \( 0 < \delta \ll 1 \), denoted by

\[
I_1 = [(1 - \delta)\sqrt{\lambda_j}, (1 + \delta)\sqrt{\lambda_j}] \cup [(-1 - \delta)\sqrt{\lambda_j}, (-1 + \delta)\sqrt{\lambda_j}], \quad I_2 = \mathbb{R} \setminus I_1.
\]

When \( a \in I_2 \), we obtain the estimate

\[
|l_\varepsilon(a)|^2 \geq s_1^2(a^2 - \lambda_j)^2 \geq s_1^2\lambda_j^2,
\]

where \( C_\lambda \) depends on the choice of \( \delta \) as well. When \( a \in I_1 \), it is clear that \( s_2(a^2 - \lambda_j) - a = O(s_2) - a \). Therefore,

\[
|l_\varepsilon(a)|^2 \geq s_1^2(a^2 - \lambda_j)^2 = [O(s_2) - a]^2 \geq \frac{a^2}{2} \geq C_\lambda \geq C_{\lambda_1}.
\]

by the smallness of \( s_1 \) and \( s_2 \). Note that the last inequality in above estimate is very wasteful but we want to get estimates comparable to the ones we have in the other pieces. The inequalities (5.9), (5.11), (5.12) and (5.13) allow that

\[
\sup_{a \in \mathbb{R}} |l_\varepsilon(a)|^{-1} \leq s_1^{-1}C_\lambda \leq \sigma^{-1}C_{\lambda, \mu}.
\]

Combing with the formulas in (5.5) and (5.6), we obtain that

\[
\Gamma_\varepsilon = \sup_{a \in \mathbb{R}} |L_\varepsilon^{-1}(a)| \leq \sigma^{n-1} \cdot \sigma^{-n}C_{\lambda, \mu} \leq \sigma^{-1}C_{\lambda, \mu}.
\]
It follows from Proposition 11 that, for $\varepsilon \in \Omega(\sigma, \mu)$,
\begin{equation}
|\varepsilon L_{\varepsilon}^{-1}(a)| \leq \sigma \cdot \sigma^{-1} C_{\lambda, \mu}.
\end{equation}
This inequality is crucial in the contraction mapping argument used in Section 5.2.

**Remark 12.** By (5.15), we see that $\Gamma_{\varepsilon}$ can be bounded by $\sigma^{-1}$ when $\sigma$ is the minimum distance to the origin in the domain $\Omega(\sigma, \mu)$. Then it follows from (5.16) that the bad factors $\sigma^{-1}$ can be dominated by the good factor $\sigma$. This is the reason why we choose $\sigma \leq |\varepsilon| \leq 2\sigma$, whose maximum and minimum distance to the origin are comparable. Note, however, that the estimate for $\varepsilon L_{\varepsilon}^{-1}(a)$ are independent of $\sigma$, so we obtain uniqueness of solutions for different $\sigma$, i.e. the solutions obtained for different $\sigma$ agree for the $\varepsilon$ in the intersection.

**Remark 13.** We note that the method presented in this present paper can accommodate small modifications leading to several generalizations. For example, we have the general equation (1.3) with $p = \text{diag}(p_1, \cdots, p_n)$, $q = \text{diag}(q_1, \cdots, q_n)$ being a diagonal matrix satisfying $p_j, q_j \in \mathbb{R} \setminus \{0\}$, $j = 1, \cdots, n$. In this general case, the only modification with the present exposition is that the calculation for $l_{\varepsilon}(a)$ in (5.10) becomes
\begin{equation}
|l_{\varepsilon}(a)|^2 = |-\varepsilon p_j a^2 + i q_j a + \varepsilon \lambda_j|^2
\end{equation}
\begin{equation}
= \left[-s_1(p_j a^2 - \lambda_j) - i(s_2 p_j a^2 - q_j a - s_2 \lambda_j)\right]^2
\end{equation}
\begin{equation}
= s_1^2(p_j a^2 - \lambda_j)^2 + \left[s_2(p_j a^2 - \lambda_j) - q_j a\right]^2,
\end{equation}
which makes no difference in our discussion in Proposition 11.

5.2. **Analyticity in $\varepsilon$ of the solution $U_{\varepsilon}$.** As the discussion in Section 2, we rewrite (2.9) as
\begin{equation}
U(\theta) = \varepsilon L_{\varepsilon}^{-1}[f(\theta) - \hat{g}(U(\theta))] \equiv T(U)(\theta)
\end{equation}
with $U$ being a function of $\varepsilon$ defined by $U_{\varepsilon} = U_{\varepsilon}(\theta)$. In addition, we define the operator $T$, acting on functions analytic in $\varepsilon$, given by
\begin{equation}
T(U) \equiv \varepsilon L_{\varepsilon}^{-1}[f - \hat{g}(U)]
\end{equation}
with $T$ being a function of $(\varepsilon, U)$. Since we want to obtain the solution $U_{\varepsilon}$ depending analytically on $\varepsilon$, we reinterpret $T$ above as an operator acting on space $H^{p, m, \Omega}$ consisting of analytic functions of $\varepsilon$ taking values in $H^{p, m}$ with $\varepsilon$ ranging over the domain $\Omega(\sigma, \mu)$. We endow the space
\begin{equation}
H^{p, m, \Omega} = \left\{U : \varepsilon \to U_{\varepsilon} : \Omega \to H^{p, m} \text{ is analytic and bounded}\right\}
\end{equation}
with the supremum norm
\begin{equation}
\|U\|_{p, m, \Omega} = \sup_{\varepsilon \in \Omega} \|U_{\varepsilon}\|_{p, m}.
\end{equation}
The supremum norm in $\varepsilon$ makes $H^{p, m, \Omega}$ a Banach space. Moreover, it is also a Banach algebra under multiplication when $m > d$ by Proposition 4.

We now show that the operator $T$ defined in (5.18) maps the space $H^{p, m, \Omega}$ into itself.
Lemma 14. Assume \( m > (d + 2) \). If \( U \in H^{\rho,m,\Omega} \), then \( T(U) \in H^{\rho,m,\Omega} \). Precisely, if the mapping \( \varepsilon \to U_\varepsilon : \Omega \to H^{\rho,m} \) is complex differentiable, then the mapping \( \varepsilon \to T_\varepsilon(U_\varepsilon) : \Omega \to H^{\rho,m} \) is complex differentiable as well.

Proof. From the definition (5.18), we know that the operator \( T \) is composed of operators \( \varepsilon L^{-1}_\varepsilon \) and \( \hat{g} \). It is clear that the map \( \varepsilon \to \hat{g}(U_\varepsilon) : \Omega \to H^{\rho,m} \) is complex differentiable since \( \hat{g} \) is analytic and it does not depend on \( \varepsilon \) explicitly. Therefore, it suffices to show that the map \( \varepsilon \to \varepsilon L^{-1}_\varepsilon(V_\varepsilon) : \Omega \to H^{\rho,m} \) is complex differentiable when \( V_\varepsilon \), considered as a function from \( \Omega \) to \( H^{\rho,m} \), is a complex differentiable.

We prove that the derivatives of \( \varepsilon L^{-1}_\varepsilon(V_\varepsilon) \) with respect to \( \varepsilon \) exist in the space \( H^{\rho,m-2} \) instead of \( H^{\rho,m} \). Then, we apply somewhat surprising Lemma 32 in the Appendix A to conclude that the derivatives we consider indeed exist in the space \( H^{\rho,m} \).

For a fixed \( \varepsilon \in \Omega \), we expand \( V_\varepsilon(\theta) \) as

\[
V_\varepsilon(\theta) = \sum_{k \in \mathbb{Z}^d} \hat{V}_{k,\varepsilon} e^{ik\cdot \theta},
\]

with

\[
(5.19) \quad \hat{V}_{k,\varepsilon} = \int_{\mathbb{T}_\rho} V_\varepsilon(\theta) e^{-ik\cdot \theta} d\theta
\]

satisfying

\[
(5.20) \quad \left| \hat{V}_{k,\varepsilon} \right| \leq \left\| V_\varepsilon \right\|_{\rho,m} e^{-\rho|k|} \left( |k|^2 + 1 \right)^{-\frac{m}{2}}.
\]

Taking the derivative with respect to \( \varepsilon \) for (5.19), we have that

\[
(5.21) \quad \frac{d}{d\varepsilon} \hat{V}_{k,\varepsilon} = \int_{\mathbb{T}_\rho} \left( \frac{d}{d\varepsilon} V_\varepsilon \right)(\theta) e^{-ik\cdot \theta} d\theta
\]

with

\[
(5.22) \quad \left| \frac{d}{d\varepsilon} \hat{V}_{k,\varepsilon} \right| \leq \left\| \frac{d}{d\varepsilon} V_\varepsilon \right\|_{\rho,m} e^{-\rho|k|} \left( |k|^2 + 1 \right)^{-\frac{m}{2}}.
\]

It follows from Section 5.1 that

\[
\varepsilon L^{-1}_\varepsilon(V_\varepsilon) = \sum_{k \in \mathbb{Z}^d} \varepsilon L^{-1}_\varepsilon(\omega \cdot k) \hat{V}_{k,\varepsilon} e^{ik\cdot \theta}
\]

with \( L^{-1}_\varepsilon \) defined in (5.5). By (5.14), we have that

\[
\left| \frac{d}{d\varepsilon} \left[ \varepsilon L^{-1}_\varepsilon(\omega \cdot k) \hat{V}_{k,\varepsilon} \right] \right| = \left| n \cdot \varepsilon^{n-1} \cdot l^{-n}_\varepsilon(\omega \cdot k) - n \cdot \varepsilon^n \cdot l^{-n-1}_\varepsilon(\omega \cdot k) \cdot \left( (\omega \cdot k)^2 + \lambda \right) \right| \leq C_{n,\lambda,\mu} \cdot \sigma^{-1}|k|^2.
\]

Together with the formulas (5.5) and (5.6), we have that

\[
(5.23) \quad \left| \frac{d}{d\varepsilon} \left( \varepsilon L^{-1}_\varepsilon(\omega \cdot k) \hat{V}_{k,\varepsilon} \right) \right| \leq \left| \frac{d}{d\varepsilon} (\varepsilon L^{-1}_\varepsilon(\omega \cdot k)) \right| \left| \hat{V}_{k,\varepsilon} \right| + \left| \varepsilon L^{-1}_\varepsilon(\omega \cdot k) \right| \left| \frac{d}{d\varepsilon} \hat{V}_{k,\varepsilon} \right| \leq C_{n,\lambda,\mu} \cdot \sigma^{-1}|k|^2 \left( \left| \hat{V}_{k,\varepsilon} \right| + \left| \frac{d}{d\varepsilon} \hat{V}_{k,\varepsilon} \right| \right).
\]
Hence, (5.20), (5.22) and (5.23) yield that
\[ \left\| \frac{d}{d\varepsilon} \left( \varepsilon^{L_{\varepsilon}^{-1}(\omega \cdot k)} \tilde{V}_{k,\varepsilon} \right) e^{ik \cdot \theta} \right\|_{p,m,-\tau} \]
\[ \leq C_{n,\lambda,\mu} \cdot \sigma^{-1} |k|^2 \left( |\tilde{V}_{k,\varepsilon}| + \left| \frac{d}{d\varepsilon} \tilde{V}_{k,\varepsilon} \right| \right) \|e^{ik \cdot \theta}\|_{p,m,-\tau} \]
\[ \leq C_{n,\lambda,\mu} \cdot \sigma^{-1} |k|^2 \left( \|V_{\varepsilon}\|_{p,m} + \left| \frac{d}{d\varepsilon} V_{\varepsilon} \right|_{p,m} \right) e^{-\rho |k| (|k|^2 + 1)^{-\frac{\tau}{2}}} \]
\[ \leq C_{n,\lambda,\mu} \cdot \sigma^{-1} \left( \|V_{\varepsilon}\|_{p,m} + \left| \frac{d}{d\varepsilon} V_{\varepsilon} \right|_{p,m} \right) (|k|^2 + 1)^{-\frac{\tau}{2}}. \]

By \( \sum_{|k| = \kappa} 1 = 2^d \kappa^{d-1}, \ k = (k_1, \ldots, k_d) \in \mathbb{Z}^d \) and choosing \( d + 2 < \tau \leq m \), we obtain that
\[ \sum_{k \in \mathbb{Z}^d} (|k|^2 + 1)^{-\frac{\tau}{2}} \leq C_d \sum_{\kappa = 0}^{\infty} (\kappa^2 + 1)^{-\frac{\tau-d-1}{2}} < \infty. \]

As a consequence, it follows from Weierstrass M-test that the series
\[ \sum_{k \in \mathbb{Z}^d} \frac{d}{d\varepsilon} \left( \varepsilon^{L_{\varepsilon}^{-1}(\omega \cdot k)} \tilde{V}_{k,\varepsilon} \right) e^{ik \cdot \theta} \]
converge uniformly on \( \varepsilon \in \Omega \) in the space \( H^{p,m,-\tau} \). The fact that these formal derivatives are uniformly convergent shows that they are the true derivatives. Namely,
\[ \frac{d}{d\varepsilon} \left( \varepsilon^{L_{\varepsilon}^{-1}(\omega \cdot k)} \tilde{V}_{k,\varepsilon} \right) e^{ik \cdot \theta}. \]

Therefore, we have that the mapping \( \varepsilon \rightarrow \varepsilon^{L_{\varepsilon}^{-1}}(V_{\varepsilon}) : \Omega \rightarrow H^{p,m,-\tau} \) is complex differentiable. Since \( H^{p,m} \subset H^{p,m,-\tau} \), we conclude that the mapping \( \varepsilon \rightarrow \varepsilon^{L_{\varepsilon}^{-1}}(V_{\varepsilon}) : \Omega \rightarrow H^{p,m} \) is complex differentiable with derivatives in \( H^{p,m,-\tau} \) by Lemma 32 in Appendix A.

5.3. **Existence of the fixed point.** The proof of the existence of the solutions for equation (5.17) is based on the fixed point theorem in the Banach space \( H^{p,m,\Omega} \). We consider a ball \( B_r(0) \) around the origin in \( H^{p,m,\Omega} \) with radius \( r > 0 \) such that \( T(B_r(0)) \subset B_r(0) \) and \( T \) is a contraction in the ball \( B_r(0) \).

By (5.16), we get
\[ \|\varepsilon^{L_{\varepsilon}^{-1}}\|_{p,m,\Omega} \leq C_{\lambda,\mu}. \]

Moreover, it follows from (2.6) (\( \hat{g}(0) = D\hat{g}(0) = 0 \)) and Proposition 6 that the Lipschitz constant of the composition operator \( \hat{g} \circ U \) is bounded by a constant times the radius \( r \) when \( U \in B_r(0) \). Therefore, for \( U \in B_r(0) \), one has
\[ \|T(U)\|_{p,m,\Omega} \leq \|T(0)\|_{p,m,\Omega} + \|T(U) - T(0)\|_{p,m,\Omega} \]
\[ \leq \|\varepsilon^{L_{\varepsilon}^{-1}}\|_{p,m,\Omega} (\|f\|_{p,m,\Omega} + \|\hat{g}(U) - \hat{g}(0)\|_{p,m,\Omega}) \]
\[ \leq C_{\lambda,\mu} (\|f\|_{p,m,\Omega} + Lip(\hat{g}) \cdot \|U\|_{p,m,\Omega}) \]
\[ \leq C_{\lambda,\mu} (\|f\|_{p,m,\Omega} + O(r) \cdot \|U\|_{p,m,\Omega}) \leq r, \]
whenever we take \( f \) and \( r \) such that
\[
\|f\|_{\rho,m,\Omega} \leq \frac{r}{2C_{\lambda,\mu}}, \quad C_{\lambda,\mu}O(r) < \frac{1}{2}.
\]
Note that we need the smallness assumption for \( f \) in this case. Thus, \( \mathcal{T}(\mathcal{B}_r(0)) \subset \mathcal{B}_r(0) \).

For any elements \( U_1, U_2 \in \mathcal{B}_r(0) \), we have that
\[
\|\mathcal{T}(U_1) - \mathcal{T}(U_2)\|_{\rho,m,\Omega} = \|\varepsilon L^{-1}_\varepsilon \hat{g}(U_1) - \varepsilon L^{-1}_\varepsilon \hat{g}(U_2)\|_{\rho,m,\Omega}
\leq C_{\lambda,\mu}O(r)\|U_1 - U_2\|_{\rho,m,\Omega}
\leq \frac{1}{2}\|U_1 - U_2\|_{\rho,m,\Omega}.
\]

Therefore, \( \mathcal{T} \) is a contraction in the ball \( \mathcal{B}_r(0) \) satisfying (5.25). It follows from the fixed point theorem in the Banach space \( H^{p,m,\Omega} \) that there exists a unique solution \( U \in H^{p,m,\Omega} \) analytic in \( \varepsilon \) for equation (2.4).

**Remark 15.** When we consider the operator \( \mathcal{T} \) defined in (5.18) in the Banach space \( H^{p,m,\Omega} \), the solution \( U_\varepsilon \) obtained via fixed point theorem does not lose any regularity on \( \varepsilon \). That is, the solution \( U_\varepsilon \) naturally depends analytically on the parameter \( \varepsilon \). However, in the finitely differentiable case, when we take \( \varepsilon \in \Omega \subset \mathbb{R} \) instead of \( \varepsilon \in \Omega \subset \mathbb{C} \), the contraction mapping principle is not enough to get a solution \( U_\varepsilon \) with optimal regularity in \( \varepsilon \) since for \( \rho = 0 \), the space \( H^{p,m,\Omega} \) is no longer a Banach space with supremum in \( \varepsilon \). We will combine with the implicit function theorem to get the optimal regularity. (See Section 6.1 for more details.) It is worth pointing out that in the low regularity, especially in \( H^1 \), we need more sophisticated contraction argument in some sense since there is no Lipschitz property for the composition operator \( \hat{g} \circ u \) in \( H^1 \). (See Section 6.2.)

**Remark 16.** We emphasize that the general solution \( U_\varepsilon \) obtained above maybe not differentiable in \( \varepsilon \) at the origin \( \varepsilon = 0 \) since we do not impose any Diophantine condition for the frequency \( \omega \). Indeed, if \( U_\varepsilon \) was differentiable, we denote the derivative \( \frac{dU_\varepsilon}{d\varepsilon}(\varepsilon = 0) \) and assume \( U_\varepsilon = 0 \) at point \( \varepsilon = 0 \). Then, taking the derivative in \( \varepsilon \) at \( \varepsilon = 0 \) for equation 2.4, \( U^{(1)}(\varepsilon) \) would satisfy that
\[
(\omega \cdot \partial \theta) U^{(1)}(\varepsilon) = f(\varepsilon).
\]
If \( \omega \) is sufficiently Liouvillean (e.g., \( |\omega \cdot k| \leq \exp(|k|^2) \)), such \( \omega \) can be easily constructed for infinitely many \( k \), we can easily construct analytic function \( f \) so that \( U^{(1)}(\varepsilon) \) solving (5.26) cannot be even a distribution.

**Lemma 17.** For the solution \( U_\varepsilon \) constructed above, we have that the mapping \( \varepsilon \to U_\varepsilon \) is continuous when \( \varepsilon \to 0 \).

**Proof.** We take \( \rho_1 > \rho > 0 \) so that both the space \( H^{p_1, m} \) and the space \( H^{p, m} \) satisfy the assumptions of the Theorem 7. Denote by \( U^1_\varepsilon \), \( U_\varepsilon \) the solutions obtained by applying Theorem 7 to \( H^{p_1, m} \), \( H^{p, m} \) respectively. Then, we observe that \( U^1_\varepsilon = U_\varepsilon \) by \( U^1_\varepsilon \in H^{p_1, m} \subset H^{p, m} \) and the uniqueness conclusion in \( H^{p, m} \). Moreover, we note that the set \( \{U^1_\varepsilon | \varepsilon \in \Omega \} \), where \( \Omega \) denotes the closure of \( \Omega \), is bounded in \( H^{p_1, m} \) and hence it is precompact in \( H^{p, m} \) topology.

To show that \( U_\varepsilon \) is continuous in \( \varepsilon \) at \( \varepsilon = 0 \), it suffices to verify that the graph \( \mathcal{G} \) of \( U \). That is,
\[
\mathcal{G} := \{(\varepsilon, U_\varepsilon) | \varepsilon \in \Omega \}
\]
is compact in the $H^{p,m}$ topology. Since a ball in $H^{p_1,m}$ is precompact in $H^{p,m}$, we just need to prove that $\mathcal{G}$ is closed. Indeed, the sequence $(\varepsilon_n, U_{\varepsilon_n}) \in \mathcal{G}$ if and only if (2.8) is satisfied, that is

$$L_{\varepsilon_n}(U_{\varepsilon_n}(\theta)) = \varepsilon_n f(\theta) - \varepsilon_n \hat{g}(U_{\varepsilon_n}(\theta)).$$

Taking the limits of $\varepsilon_n \to \varepsilon^*$, $U_{\varepsilon_n} \to U^*$ for $n \to \infty$, one can obtain that

$$L_{\varepsilon^*}(U^*(\theta)) = \varepsilon^* f(\theta) - \varepsilon^* \hat{g}(U^*(\theta)).$$

Hence, we conclude that $(\varepsilon^*, U^*) \in \mathcal{G}$. □

6. Finitely differentiable case: Proofs of Theorem 9 and Theorem 10

In this section we present the proof of Theorem 9, which concerns the highly differentiable forcing $f$. We also prove Theorem 10 in which the forcing is assumed to be $L^2$ or $H^1$. The method used for the finitely differentiable case, especially $H^1$, is different from that for the analytic case.

6.1. Proof of Theorem 9. When the forcing term $f$ and the nonlinear term $g$ are finitely differentiable, we consider $\varepsilon \in \mathbb{R}$ in equation (1.1).

6.1.1. Regularity in $\varepsilon$. In order to get solutions $U_{\varepsilon}$ with some regularity in $\varepsilon$, we need to consider the operator $T$ defined in (2.9) acting on the space $H^{m,\tilde{\Omega}}$ consisting of differentiable functions of $\varepsilon$ taking values in $H^m$ with $\varepsilon$ ranging over the domain $\tilde{\Omega}$ defined in (4.2). Moreover, we endow $H^{m,\tilde{\Omega}}$ with the supremum norm

$$(6.1) \quad \|U\|_{H^{m,\tilde{\Omega}}} = \sup_{\varepsilon \in \tilde{\Omega}} \|U_\varepsilon\|_{H^m},$$

which is similar to the analytic case in Section 5.2. Note that $H^m$ is a Banach space and it is a Banach algebra when $m > \frac{d}{2}$ by Proposition 4. However, $H^{m,\tilde{\Omega}}$ (in contrast with the analytic version $H^{\rho,m,\tilde{\Omega}}$) is not a Banach space with the supremum norm defined in (6.1). In this case, if we just apply the fixed point theorem to the proof of Theorem 9 in the space $H^{m,\tilde{\Omega}}$, we may lose some regularity in the argument $\varepsilon$. To avoid this shortcoming, we will combine the contraction argument with the implicit function theorem such that the solution $U_{\varepsilon}$ with optimal regularity in $\varepsilon$ can be obtained.

More precisely, as shown in Section 6.1.2 at Step 1, for some $\varepsilon_0 \in \tilde{\Omega}$, we first produce a solution $U_{\varepsilon_0}$ of equation (2.9) such that $T(\varepsilon_0, U_{\varepsilon_0}) = 0$, where $T$ is defined in (2.10). To get the optimal regularity of the map taking $\tilde{\Omega}$ to $H^m$, we apply the classic implicit function theorem (we refer to the references [Die69, LS90, KP13]) for the operator $T$. In this process, it is crucial to study the differentiability of the operator $T$, mapping $\Omega \times H^m$ to $H^m$, with respect to the arguments $(\varepsilon, U)$ as well as the invertibility of $D_2 T(\varepsilon_0, U_{\varepsilon_0})$.

By equation (2.9), we can easily get the differentiability of the operator $T$ with respect to the argument $U \in H^m$ since the operator $L_\varepsilon$ are linear and the differentiability properties of the left composition operator $\hat{g} \circ U$ are already studied carefully in [IKT13, AZ90].

The key to our results will be the differentiability of the operator $T$ in (2.9) with respect to $\varepsilon$ as the following:
Proposition 18. Fix any \( m \in \mathbb{N} \) with \( m > \frac{d}{2} \) and \( \sigma > 0 \). We consider the map 
that \( \varepsilon L_{\varepsilon}^{-1} \in B(H^m, H^m) \) for every \( \varepsilon \in \tilde{\Omega} \), where \( B(H^m, H^m) \) denotes the set of bounded operators from the space \( H^m \) to itself.

For any \( l \in \mathbb{N} \), the map \( \varepsilon \rightarrow \varepsilon L_{\varepsilon}^{-1} \) is \( C^l \) considered as a mapping from \( \tilde{\Omega} \) to \( B(H^m, H^m) \). Moreover, for any \( l \in \mathbb{N} \) and \( \varepsilon \in \tilde{\Omega} \), \( \frac{d}{d\varepsilon}(\varepsilon L_{\varepsilon}^{-1}) \in B(H^m, H^m) \).

As a matter of fact, something stronger is true. The map \( \varepsilon \rightarrow \varepsilon L_{\varepsilon}^{-1} \) is real analytic for \( \varepsilon \in \tilde{\Omega} \) and the radius of analyticity can be bounded uniformly for all \( \varepsilon \in \Omega \).

Proof. The key to the proof is the observation that, as noted in (5.8) in Section 5.1.2, 
\[ |l_\varepsilon(a)| \geq |\varepsilon| |\lambda_j| \geq \sigma |\lambda_j| \quad \text{for} \quad \varepsilon \in \tilde{\Omega}. \]

To study the expansion in powers of \( \delta \) for \( l_{\varepsilon+\delta}^{-1}(a) \), we rewrite:
\[
l_{\varepsilon+\delta}^{-1}(a) = ((\varepsilon + \delta)(\lambda_j - a^2) + ia)^{-1} \\
= (\varepsilon(\lambda_j - a^2) + ia + \delta(\lambda_j - a^2))^{-1} \\
= (\varepsilon(\lambda_j - a^2) + ia)^{-1} \left( 1 + \delta \frac{\lambda_j - a^2}{\varepsilon(\lambda_j - a^2) + ia} \right)^{-1}.
\]

It is easy to see that the factor \( \frac{\lambda_j - a^2}{\varepsilon(\lambda_j - a^2) + ia} \) is bounded uniformly in \( a \) (compute the limit as \( |a| \) tends to infinity and observe that the function is continuous in \( a \) since the denominator does not vanish) and uniformly in \( \varepsilon \) when \( \varepsilon \) ranges in an interval bounded away from zero.

Therefore, we can expand \( \left( 1 + \delta \frac{\lambda_j - a^2}{\varepsilon(\lambda_j - a^2) + ia} \right)^{-1} \) in (6.2) in powers of \( \delta \) using the geometric series formula. Moreover, the radii of convergence are bounded uniformly in \( \varepsilon \in \tilde{\Omega} \) and the values of the coefficients in the expansion are also bounded uniformly in \( a \in \mathbb{R}, \varepsilon \in \tilde{\Omega} \).

Using the formula (5.6) in Section 5.1.1 for the inverse \( L_{\varepsilon}^{-1} \), we also obtain that the matrices \( L_{\varepsilon+\delta}^{-1} \) can be expanded in powers of \( \delta \) with coefficients that are bounded uniformly in \( a \in \mathbb{R}, \varepsilon \in \tilde{\Omega} \).

We note that the operator \( L_{\varepsilon}^{-1} \) are multiplier operators (in the sense used in Fourier series). That is, for \( \hat{f}_k \) being the Fourier coefficients of function \( f \) in the space \( H^m \), the Fourier coefficients \( \left( L_{\varepsilon}^{-1}f \right)_k \) of function \( (L_{\varepsilon}^{-1}f) \) in the space \( H^m \) have the structure:
\[
\left( L_{\varepsilon}^{-1}f \right)_k = L_{\varepsilon,k}^{-1} \hat{f}_k,
\]
where each \( L_{\varepsilon,k}^{-1} \) is \( n \times n \) matrix (see (5.6) for details). From the discussion in above paragraph, we know that, for each \( k \), \( L_{\varepsilon,k}^{-1} \) is uniformly analytic in \( \varepsilon \). Thus, we conclude that the operator \( L_{\varepsilon}^{-1} \) is analytic in \( \varepsilon \) by (6.3).

In addition, we know that the Fourier indices \( k \) only enter into the multipliers \( L_{\varepsilon,k}^{-1} \) through \( \omega \cdot k \) and the supremum of \( L_{\varepsilon,k}^{-1} \) over the Fourier index is bounded by the supremum in \( a \), which is studied in the previous Section 5.1. Together with the fact that the norms of functions in Sobolev spaces are measured by size of the Fourier coefficients, we have that, for all \( m > \frac{d}{2} \), the norm of \( L_{\varepsilon}^{-1} \) considered as an operator from the Sobolev space \( H^m \) to itself is defined by
\[
\|L_{\varepsilon}^{-1}\|_{H^m \rightarrow H^m} = \sup_{k \in \mathbb{Z}^d} \|L_{\varepsilon,k}^{-1}\|.
\]
Note that the norms of $L_{\varepsilon,k}^{-1}$ are just finite-dimensional norms. As a consequence, we can bound $\|L_{\varepsilon}^{-1}\|_{H^m\to H^m}$ by the supremum of the multipliers defined in (6.4). Therefore, when we write $L_{\varepsilon+\delta}^{-1} = \sum_{n=0}^{\infty} L_{\varepsilon,n}^{-1} \delta^n$, $\|L_{\varepsilon,n}^{-1}\|_{H^m\to H^m}$ can be bounded by the way of (6.4). That means $\frac{d}{d\varepsilon}(\varepsilon L_{\varepsilon}^{-1}) \in B(H^m, H^m)$ for every $\varepsilon \in \bar{\Omega}$. □

6.1.2. Existence of the solutions. With all the above preliminaries established, now we turn to finishing the proof of Theorem 9. We divide the proof into two steps. First, for a fixed $\varepsilon \in \bar{\Omega}$, we find a fixed point $U_\varepsilon$ of $T$ defined in (2.9) by considering a domain $P \subset H^m$ with $T(P) \subset P$ on which $T$ is a contraction. Secondly, we use the classical implicit function theorem to verify that the solution $U_\varepsilon$ we obtained in the first step possesses the optimal regularity in $\varepsilon$. Namely, we conclude that $U_\varepsilon \in H^m(\bar{\Omega})$.

Step 1. As we state in Section 2.4, there are two ways to prove that $T$ is a contraction. One is that we choose a small ball in $H^m$ such that $\text{Lip}(\hat{g})$ is small in this ball. Meanwhile, we impose smallness condition on $f$ in this ball. In this way, the operator $T$ maps this ball into itself and it is a contraction in this ball. (We omit the details here since it is similar to Section 5.3). Another is that we assume that $\text{Lip}(\hat{g})$ (or $D\hat{g}$) is globally small in the whole of $\mathbb{R}^n$. In this case, for a fixed $\varepsilon \in \bar{\Omega}$ and $U_1, U_2 \in H^m$, it follows from (5.24) that

$$\|T(U_1) - T(U_2)\|_{H^m} = \|\varepsilon L_{\varepsilon}^{-1}(\hat{g}(U_1) - \hat{g}(U_2))\|_{H^m} \leq C_{\lambda,m} \text{Lip}(\hat{g}) \cdot \|U_1 - U_2\|_{H^m} \leq \frac{1}{2}\|U_1 - U_2\|_{H^m}.$$ 

This makes $T$ a contraction in the whole space $H^m$.

In summary, we get a fixed point $U_{\varepsilon_0} \in H^m$ of the equation (5.18) for some $\varepsilon_0 \in \bar{\Omega}$.

Step 2. It follows from Proposition 6 and Proposition 18 that the operator $T$ is $C^l$ with respect to the argument $(\varepsilon,U)$. Namely, $T(\varepsilon,U) := U - T(\varepsilon,U)$ is $C^l$ in the domain of $\bar{\Omega} \times H^m$. Based on Step 1, we have $T(\varepsilon_0, U_{\varepsilon_0}) = 0$. Moreover, $D_2T(\varepsilon_0, U_{\varepsilon_0}) = Id - D_2T(\varepsilon_0, U_{\varepsilon_0}) = Id - \varepsilon_0 L_{\varepsilon_0}^{-1} D\hat{g}(U_{\varepsilon_0})$ is invertible since $\varepsilon_0 L_{\varepsilon_0}^{-1}$ is bounded and $D\hat{g}(U_{\varepsilon_0})$ is sufficiently small. Therefore, by the implicit function theorem, there exist an open neighborhood included in $\bar{\Omega} \times H^m$ of $(U_{\varepsilon_0}, \varepsilon_0)$ and a $C^l$ function $U_\varepsilon$ satisfying $T(\varepsilon, U_\varepsilon) = 0$ on this neighborhood.

6.2. Proof of Theorem 10. In this section, we will prove Theorem 10 in a different way from the first two cases (analytic and highly differentiable cases). The key problem is the properties of the composition operator $\hat{g} \circ u$ in space $H^1(\mathbb{T}^d)$ or space $L^2(\mathbb{T})$.

Proposition 19. For the composition operator defined by:

$$C_{\hat{g}}[u](\theta) = \hat{g}(u(\theta)),$$

we have the following properties:

If we consider $C_{\hat{g}}$ acting on $L^2(\mathbb{T}^d, \mathbb{R}^n)$ and assume that $\hat{g}$ is globally Lipschitz continuous on $\mathbb{R}^n$, then

$$C_{\hat{g}} : L^2(\mathbb{T}^d, \mathbb{R}^n) \to L^2(\mathbb{T}^d, \mathbb{R}^n)$$

is Lipschitz continuous.
If we consider $C_\hat{g}$ acting on $H^1(\mathbb{T}^d, \mathbb{R}^n)$ and assume that $\hat{g} \in C^{1+\text{Lip}}$, then

$$C_\hat{g} : H^1(\mathbb{T}^d, \mathbb{R}^n) \to H^1(\mathbb{T}^d, \mathbb{R}^n)$$

is bounded and continuous. In particular, given $\varepsilon > 0$, there is $\delta := \delta(\varepsilon, \text{Lip}(\hat{g}), \hat{g}(0)) > 0$ so that $\|u\|_{H^1} \leq \delta$ implies $\|C_\hat{g}(u)\|_{H^1} \leq \varepsilon$.

**Proof.** Since $\hat{g}$ is globally Lipschitz continuous on $\mathbb{R}^n$, denote $M = \text{Lip}(\hat{g})$ (for ease of notation, we will use $M$ in the following part) and for $u, v \in L^2(\mathbb{T}^d, \mathbb{R}^n)$, we get

$$|\hat{g}(u(\theta)) - \hat{g}(v(\theta))| \leq M|u(\theta) - v(\theta)|.$$

Therefore,

$$\|\hat{g} \circ u - \hat{g} \circ v\|_{L^2} \leq M\|u - v\|_{L^2}.$$

We refer to [AZ90, KS00] for the properties of the operator $C_\hat{g}$ mapping space $H^1(\mathbb{T}^d, \mathbb{R}^n)$ to itself. $\square$

**Remark 20.** We emphasize that for our results in $L^2$ and $H^m$ ($m > \frac{d}{2}$), it is needed to assume that $M = \text{Lip}(\hat{g})$ is globally arbitrary small. This allows us to obtain that the operator $T$ in (2.9) is a contraction in the whole space.

However, due to the lack of Lipschitz regularity for the operator $C_\hat{g}$ acting on the space $H^1$ (see [AZ90]), we need to choose a ball belonging to $H^1$ so that the operator $T$ maps this ball into itself. Note that the chosen ball does not need to be small. We also do not require that the forcing is small in $H^1$.

Now, we go back to the proof of Theorem 10.

**Proof.** First we give the proof for the result in space $L^2$. By Parseval’s identity, we know that the $L^2$-norm is also expressible in terms of the Fourier coefficients. Together with the bound of $\varepsilon L_{\mathbb{C}}^{-1}$ in (5.24), we have that $T(L^2) \subset L^2$. Also, for $u, v \in L^2$, one has

$$\|T(u) - T(v)\|_{L^2} = \|\varepsilon L_{\mathbb{C}}^{-1}(\hat{g} \circ u - \hat{g} \circ v)\|_{L^2} \leq C_{\lambda,\mu} M \|u - v\|_{L^2}.$$

It follows from $M := \text{Lip}(\hat{g}) \ll 1$ in assumption $\tilde{H}$ that $T$ is a contraction in $L^2$. This gives the $L^2$ result.

Now, we present the proof for the result in $H^1$. Using the interpolation inequality in Lemma 3, we obtain, for $n \leq 1$, that

$$\|T^{n+1}(u) - T^n(u)\|_{H^s} \leq C_{\lambda,\mu} |T^{n+1}(u) - T^n(u)|_{L^2}^{1-s} \|T^{n+1}(u) - T^n(u)\|_{H^1}^s,$$

$$\leq C_{\lambda,\mu} (M^n)^{1-s} \|T(u) - u\|_{L^2}^{1-s} \|T^{n+1}(u) - T^n(u)\|_{H^1}^s.$$

We have that the function $(M^n)^{1-s}$ is decreasing exponentially.

The remaining task is to show that $\|T^{n+1}(u) - T^n(u)\|_{H^1}$ in (6.6) can be bounded independently of the iteration step $n$. As a matter of fact, from Proposition 19, we know that $u \in H^1$ implies $\hat{g} \circ u \in H^1$. Moreover, it is easy to check that

$$\|\hat{g} \circ u\|_{H^1} \leq M\|u\|_{H^1}.$$

Therefore, for the operator $T$ defined in (2.9), we get

$$\|T(u)\|_{H^1} = \|\varepsilon L_{\mathbb{C}}^{-1}(f + \hat{g} \circ u)\|_{H^1} \leq C_{\lambda,\mu} \|f\|_{H^1} + C_{\lambda,\mu} M \|u\|_{H^1}.$$
We now choose a ball $B_r(0)$ centered at the origin in $H^1$ such that $B_r(0)$ is mapped by $T$ into itself. This can be achieved whenever we take $r$ such that $C_{\lambda, \mu} \|f\|_{H^1} + C_{\lambda, \mu} Mr \leq r$, which is equivalent to

$$r \geq \frac{C_{\lambda, \mu} \|f\|_{H^1}}{1 - C_{\lambda, \mu} M}. \tag{6.7}$$

This can be done since $M$ is small enough. Note that the radius $r$ chosen by (6.7) depends on the function $f$, which can be any function in $H^1$. As a consequence, for every $u \in B_r(0)$ and $n \in \mathbb{N}$, we obtain that $T^n(u) \in B_r(0)$ and

$$\|T^{n+1}(u) - T^n(u)\|_{H^1} \leq 2r.$$

Thus, (6.6) becomes

$$\|T^{n+1}(u) - T^n(u)\|_{H^s} \leq C_{\lambda, \mu} (M^n)_{1-s}^s (2r)^s \|T(u) - u\|_{L^2}^{1-s}, \tag{6.8}$$

which indicates that the sequence $T^n(u)$ has a limit $u^* \in H^s$ and the fixed point obtained by the contraction mapping in $L^2$ should be in $H^s$. Note that (6.8) allows one to bound the distance in $H^s$ from an initial guess to the true solution. That is,

$$\|u^* - u\|_{H^s} = \lim_{n \to 0} \|T^n(u) - u\|_{H^s} \leq \sum_{n=0}^{\infty} \|T^{n+1}(u) - T^n(u)\|_{H^s} \leq C_{\lambda, \mu} (2r)^s \|T(u) - u\|_{L^2}^{1-s} \leq C_{\lambda, \mu} (2r)^s (1 - M^{1-s})^{-1} \|T(u) - u\|_{L^2}^{1-s}.$$

□

**Remark 21.** As shown in [AZ90], the conditions for composition operators mapping $H^{1+\delta}$ to itself are very strict. There are many mapping results for the composition in $H^{1+\delta} \cap L^\infty$, but it is not clear how the $L^\infty$ norm behaves under the Fourier multipliers.

Therefore, using the methods of this paper, it seems that there is gap between the treatments possible for the forcing. Either $H^s$ ($0 < s \leq 1$) or $H^m$ ($m > d/2$).

7. Results for PDEs

An important observation is that, since the treatment of (1.1) did not use any properties of the dynamics of equation, we can treat even ill-posed partial differential equations. The ill-posed equation (1.2) is a showcase of the possibilities of our method for model (1.1). The heuristic principle is that we can think of evolutionary PDE as models similar to (1.1) in which the role of the phase space $\mathbb{R}^n$ is taken up by a function space (of functions of the spatial variable $x$). Note that the nonlinearities in PDE models can be not just compositions but more complicated operators (even unbounded). For example, the non-linearity $(u^2)_{xx}$ in equation (1.2) is an unbounded operator from a function space to itself. However, the fixed point problem under consideration in the Banach space we choose overcomes this tricky problem. (See Section 7.3).
The solutions produced in this section point in the direction that ill-posed equations, even if, lack a general theory of the existence and uniqueness of the solution, may admit many solutions that have a good physical interpretation.

For convenience, we rewrite equation (1.2) as

$$
\varepsilon u_{tt} + u_t - \varepsilon \beta u_{xxxx} - \varepsilon u_{xx} = \varepsilon (u^2)_{xx} + \varepsilon f(\omega t, x), \quad x \in T, \ t \in \mathbb{R}, \ \beta > 0
$$

with periodic boundary condition.

We define the full Lebesgue measure set

$$
O = \left\{ \beta > 0 : \frac{1}{\sqrt{\beta}} \text{ is not an integer} \right\}
$$

Note that we shall only work with values of $\beta$ in $O$ so that the eigenvalues of the linear operator $\varepsilon \beta \partial_{xxxx} + \varepsilon \partial_{xx}$ in (7.1) are different from zero in a such way that the operator $N_\varepsilon$ defined in (7.5) is invertible. (See Section 7.3 for the details).

**Remark 22.** There are other models of friction besides the $u_t$ term in (7.1) that one could consider. The treatment given in the present paper is a very general method and could be applied to several friction models, such as $u_{txx}$.

We note also that our method for the ill-posed equation (7.1) with positive parameter $\beta$ also applies to well-posed equation (7.1) with negative parameter $\beta$. It is even easier for well-posed case since the eigenvalues of the linear operator $\varepsilon \beta \partial_{xxxx} + \varepsilon \partial_{xx}$ in (7.1) are not zero such that we can invert the operator $N_\varepsilon$ defined in (7.5).

However, we just consider the ill-posed model (7.1) that serves as motivation for the readers. This ill posed case is what appears in water wave theory [Bou72].

### 7.1. Formulation of the fixed point problem.

Similar to Section 2 for ODE model, we need to reduce the equation (7.1) to a fixed point problem. In this section, we just present the formal manipulations omitting specification of spaces. Indeed, the precise spaces defined in Section 7.2 will be motivated by the desire to justify the formal manipulations and that the operators considered are a contraction.

Our goal is to find response solutions of the form

$$
u_\varepsilon(t,x) = U_\varepsilon(\omega t, x),
$$

where, for each fixed $\varepsilon$, $U_\varepsilon : T^d \times T \to \mathbb{R}$. Inserting (7.3) into (7.1), we get the following functional equation for $U_\varepsilon$:

$$
\varepsilon (\omega \cdot \partial_{\theta})^2 U_\varepsilon(\theta, x) + (\omega \cdot \partial_{\theta}) U_\varepsilon(\theta, x) - \varepsilon \beta \partial_4^2 U_\varepsilon(\theta, x) - \varepsilon \partial_2^2 U_\varepsilon(\theta, x)
\quad = \varepsilon (U^2_\varepsilon)_{xx} + \varepsilon f(\theta, x).
$$

The solution of equation (7.4) will be the centerpiece of our treatment.

Denote by $\mathcal{N}_\varepsilon$ the linear operator

$$
\mathcal{N}_\varepsilon U_\varepsilon(\theta, x) = \left[ \varepsilon (\omega \cdot \partial_{\theta})^2 + (\omega \cdot \partial_{\theta}) - \varepsilon \beta \partial_4^2 - \varepsilon \partial_2^2 \right] U_\varepsilon(\theta, x).
$$

Then, (7.4) can be rewritten as

$$
\mathcal{N}_\varepsilon U_\varepsilon(\theta, x) = \varepsilon (U^2_\varepsilon)_{xx} + \varepsilon f(\theta, x).
$$

As we will see in Section 7.3, the operator $\mathcal{N}_\varepsilon$ is boundedly invertible in some appropriate space for $\varepsilon \in \Omega(\sigma, \mu)$ defined in (4.1). Namely, (7.6) becomes

$$
U_\varepsilon(\theta, x) = \varepsilon \mathcal{N}_\varepsilon^{-1} [(U^2_\varepsilon)_{xx} + f(\theta, x)] \equiv \mathcal{T}_\varepsilon(U_\varepsilon(\theta, x),)
$$
where, for convenience, we introduce the operator $T_\varepsilon$. In Section 7.4 dealing with the analytic case, we will show that there exists a solution $U_\varepsilon$ analytic in $\varepsilon$ for equation (7.7) by the contraction mapping argument. Moreover, in Section 7.5 carrying out finitely differentiable case, we will combine contraction mapping principle with the classical implicit function theorem to get the regular results.

From the formal manipulation above, we find that the first key point is to study the invertibility of the operator $N_\varepsilon$ and give quantitative estimates on its inverse for $\varepsilon$ in a complex domain. Note that the linear operator $N_\varepsilon$ defined in (7.5) used to study PDE models is much more complicated than the linear operator $L_\varepsilon$ defined in (2.7) for ODE models since $N_\varepsilon$ involves not only the angle variable $\theta \in \mathbb{T}^d$ but also the space variable $x \in \mathbb{T}$. This leads to different calculation for the inverse of $N_\varepsilon$ (See Section 7.3).

The second crucial part is that the nonlinearity $(U_\varepsilon^2)_{xx}$ maybe unbounded from one space to itself. However, it happens that $\varepsilon N_\varepsilon^{-1}(U_\varepsilon^2)_{xx}$ is bounded. (See Lemma 25 and Lemma 26 for more details).

To get a fixed point for equation (7.7), analogous to the smallness arguments in Section 2.4 for ordinary partial differential equation (1.1), we also need to impose some smallness conditions for partial differential model. However, we only consider a specially nonlinear map $U \rightarrow \varepsilon N_\varepsilon^{-1}(U_\varepsilon^2)_{xx}$, which is analytic, be a contraction in a domain that contains a ball around $\varepsilon N_\varepsilon^{-1}f$. It is nontrivial to choose a sufficiently small ball and the forcing $f$ is assumed to be small in this ball.

### 7.2. Choice of spaces and the statement of our results

In this section, we give the concrete spaces we work in. Again, we note that the main principle is that the norms of the functions needed to be expressed in terms of the Fourier coefficients associated to the Fourier basis in arguments $\theta$ and $x$. This permits us to estimate the inverse of the linear operator $N_\varepsilon$ just by estimating its Fourier coefficients. We also need these spaces to possess the Banach algebra properties and the properties of composition operator so that the nonlinear terms can be controlled. From the point of view analyticity in $\varepsilon$, it is necessary to define spaces consisting of analytic functions with respect to $\varepsilon$.

In a way analogous to the definition in Section 3, for $\rho \geq 0$, $m, d \in \mathbb{Z}_+$, we define the space of analytic functions $U$ in $\mathbb{T}^{d+1}_\rho$ with finite norm\[ \|U\|_{\rho, m}^2 = \sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}} |\hat{U}_{k,j}|^2 e^{2\rho(|k|+|j|)}(|k|^2 + |j|^2 + 1)^m < +\infty \]

It is obvious that the space $\mathcal{H}_{\rho, m}$ is a Banach space as well as a Hilbert space.

We actually consider $\mathcal{H}_{0, m}$, which is a subspace of $\mathcal{H}_{\rho, m}$, consisting of functions $U \in \mathcal{H}_{\rho, m}$ with\[ \int_0^{2\pi} U(\theta, x)dx = 0. \]

In the physical applications, we also consider the closed subspace of $\mathcal{H}_{\rho, m}$ in which the functions take real values for real arguments.
Note that the choice of the normalization condition (7.8) is motivated by the assumption that
\[ \int_0^{2\pi} f(\theta, x) dx = 0. \]
Here and after, we consider our fixed point problems in the space \( H_0^{\rho,m} \). To simplicity the notation, we still write \( H^{\rho,m} \) as \( H^{\rho,m}_0 \).

For \( \rho > 0 \), \( H^{\rho,m} \) consists of functions which are analytic in the domain \( T^d_{\rho + 1} \). For \( \rho = 0 \), \( H^m := H^{0,m} \) is just the regular Sobolev space.

Similar to Proposition 4, when \( \rho > 0 \), \( m > (d + 1) \) or \( \rho = 0 \), \( m > \frac{d+1}{2} \), we still have the Banach algebra properties in space \( H^{\rho,m} \).

Now we are ready to state our main results on the existence of quasi-periodic solutions for PDE (7.1) in the cases of analyticity and finite differentiability.

**Theorem 23.** Assume that \( f \in H^{\rho,m}(T^{d+1}) \) with \( \rho > 0 \), \( m > (d + 1) \). Then, for \( \varepsilon \in \Omega(\sigma, \mu) \) defined in (4.1), there exists a unique solution \( U_\varepsilon \in H^{\rho,m}(T^{d+1}) \) for equation (7.4).

Furthermore, considering \( U_\varepsilon \) as a function of \( \varepsilon \), we have that \( \varepsilon \to U_\varepsilon : \Omega \to H^{\rho,m} \) is analytic when \( m > (d + 5) \). In addition, when \( \varepsilon \to 0 \), the solution \( U_\varepsilon \to 0 \) and \( \varepsilon \to U_\varepsilon \) is continuous.

Our method also applies to finitely differentiable forcing, but we leave the details.

**Theorem 24.** Assume that \( f \in H^m(T^{d+1}) \) with \( m > \frac{d+1}{2} \). Then, for \( \varepsilon \in \tilde{\Omega} \) defined in (4.2), there exists a unique solution \( U_\varepsilon \in H^m(T^{d+1}) \) for equation (7.4).

Furthermore, for any \( l \in \mathbb{N} \), the map \( \varepsilon \to U_\varepsilon : \tilde{\Omega} \to H^m \) is \( C^l \) (even real analytic) considered as a mapping from \( \tilde{\Omega} \) to \( H^m \). In addition, when \( \varepsilon \to 0 \), the solution \( U_\varepsilon \to 0 \) and the map \( \varepsilon \to U_\varepsilon \) is continuous.

### 7.3. The boundness of the operator \( T_\varepsilon \) defined in (7.7) taking \( H^{\rho,m} \) into itself.

For the PDE model (7.1), the nonlinear map \( U \to (U^2)_{xx} \) (which in the ODE case was a composition operator with \( \hat{g} \circ U \)) is an unbounded operator from a space to itself. We will show, however, that the map \( U \to \varepsilon N_\varepsilon^{-1}(U^2)_{xx} \) is bounded from a space to itself. To this end, we give the following lemmas and propositions. Some of the results would generalize for a nonlinearity of the form \( U \to (g(U))_{xx} \). We will not pursue these specialized results in this paper, but we think it would be an interesting subject.

**Lemma 25.** Let \( U \in H^{\rho,m} \). Denote by
\[ h(U) = (U^2)_{xx}. \]
Then, \( h \) is analytic from the space \( H^{\rho,m} \) to the space \( H^{\rho,m-2} \). Moreover, for \( V \in H^{\rho,m} \), we have that
\[ \| Dh(U) V \|_{\rho,m-2} \leq 2 \| U \|_{\rho,m} \| V \|_{\rho,m}. \]

**Proof.** We rewrite \( h = h_1 \circ h_2 \) with
\[ h_1 : H^{\rho,m} \to H^{\rho,m-2}, \quad U \to U_{xx} \]
and
\[ h_2 : H^{\rho,m} \to H^{\rho,m}, \quad U \to U^2. \]
It is obvious that both $h_1$ and $h_2$ are analytic. Therefore, the composition operator $h : \mathcal{H}^{p,m} \to \mathcal{H}^{p,m-2}$ is analytic. Moreover,

$$Dh(U)V = \frac{d}{d\xi} h(U + \xi V) \bigg|_{\xi=0} = \frac{d}{d\xi} ((U + \xi V)^2)_{xx} \bigg|_{\xi=0} = 2(UV)_{xx},$$

which shows that

$$\|Dh(U)V\|_{p,m-2} \leq 2\|UV\|_{p,m} \leq 2\|U\|_{p,m}\|V\|_{p,m}$$

by the Banach algebra property in the space $\mathcal{H}^{p,m}$.

Lemma 25 allows that the map $U \to (U^2)_{xx}$ is bounded from the space $\mathcal{H}^{p,m}$ to $\mathcal{H}^{p,m-2}$. To prove the boundedness of the operator $T_\varepsilon$ defined in (7.7), the remaining task is to show that $\varepsilon \mathcal{N}_\varepsilon^{-1} : \mathcal{H}^{p,m-2} \to \mathcal{H}^{p,m}$ is bounded.

**Lemma 26.** For a fixed $\varepsilon \in \Omega(\sigma, \mu)$, the operator $\varepsilon \mathcal{N}_\varepsilon^{-1}$ taking the space $\mathcal{H}^{p,m-2}$ into $\mathcal{H}^{p,m}$ is bounded.

**Proof.** We verify that $\|\varepsilon \mathcal{N}_\varepsilon^{-1}\|_{\mathcal{H}^{p,m-2} \to \mathcal{H}^{p,m}}$ can be bounded by the supremum of its multipliers, as we argued in the proof of Proposition 18.

For $V \in \mathcal{H}^{p,m-2}$, by (7.5) and (7.8), we have the following Fourier expansion

$$\mathcal{N}_\varepsilon^{-1}(V(\theta, x)) = \sum_{j \in \mathbb{Z}^d, \{0\}} \frac{1}{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)} \tilde{V}_{k,j} e^{i(k \cdot \theta + j \cdot x)}.$$

Note that, by (7.2), $\beta j^4 - j^2 \neq 0$ for $j \in \mathbb{Z} \setminus \{0\}$.

To obtain the desired results, we now estimate the supremum of $\tilde{N}_\varepsilon$ defined by

(7.10)

$$\tilde{N}_\varepsilon(k, j) := \frac{k^2 + j^2}{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)}$$

$$= \left(\frac{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)}{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)} + \frac{j^2}{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)}\right)$$

for $k \in \mathbb{Z}^d, j \in \mathbb{Z} \setminus \{0\}$. In fact, (7.10) includes two terms, which have similar estimates, we just give the details for the second term. Note that it is an easy case for $k = 0$. We will estimate the infimum of

$$N_\varepsilon(a,t) := \frac{-\varepsilon a^2 + i a - \varepsilon(\beta t^2 - t)}{t}, a := (k \cdot \omega) \in \mathbb{R} \setminus \{0\}, t := j^2 \in \mathbb{Z}_+.$$

Taking $\varepsilon = s_1 + is_2 \in \Omega(\sigma, \mu)$, we have

(7.11)

$$|N_\varepsilon(a,t)|^2 = s_1^2 \left[\frac{a^2}{t} - (1 - \beta t)\right]^2 + \left[s_2 \left(\frac{a^2}{t} - (1 - \beta t)\right) - \frac{a}{t}\right]^2,$$

which has an infimum controlled by $\sigma$ by a similar argument to Proposition 11. We now estimate (7.11). When $\beta > 1$, we have that $1 - \beta t < 0$. Thus, $|N_\varepsilon(a,t)|^2 \geq s_1^2 \left[\frac{a^2}{t} - (1 - \beta t)\right]^2 \geq (\beta - 1)^2 s_2^2 := s_2^2 C_\beta$ for a positive constant $C_\beta$ depending on $\beta$. In the following part, to simplify the notation, we denote $C_\beta$ by all constants depending on $\beta$.

We focus mainly on the case of $0 < \beta < 1$. We divide $t \in \mathbb{Z}_+$ into two regions as the following:
Therefore, we just consider the finitely differentiable version with $m > \frac{d+1}{2}$. In (7.7) is analytic from the space $H$ will be used in the later finitely differentiable case (see Lemma 29).

Note that the previous Lemma 26 includes the case of Remark 27.

An analogue of the low regularity results for ODE case would be easier to consider.

for a positive constant $C$

\begin{equation}
\frac{a^2}{t} - (1 - \beta t) \geq s_1^2 C_\beta.
\end{equation}

\textbf{Case 2.} When $1 \leq t \leq \left[ \frac{1}{\beta} \right]$, we get that $t(1 - \beta t) \in [C^1_{\beta} , C^2_{\beta}]$ with $C^2_{\beta} \geq C^1_{\beta} > 0$.

It is clear that \( a^2 - (1 - \beta t) = 0 \) holds at $a^2 = t(1 - \beta t) \in [C^1_{\beta} , C^2_{\beta}]$, namely, $a \in [-\sqrt{C^2_{\beta}}, -\sqrt{C^1_{\beta}}] \cup [\sqrt{C^1_{\beta}}, \sqrt{C^2_{\beta}}]$. Now, we define two regions in $a \in \mathbb{R}$, by choosing a constant $0 < \delta \ll 1$, as follows

\[ I_1 = [(-1 - \delta) \sqrt{C^2_{\beta}}, (1 + \delta) \sqrt{C^1_{\beta}}] \cup [(1 - \delta) \sqrt{C^1_{\beta}}, (1 + \delta) \sqrt{C^2_{\beta}}], \quad I_2 = \mathbb{R} \setminus I_1. \]

The case of $a \in I_2$ yields that

\[ |N_\varepsilon(a, t)|^2 \geq s_1^2 \left[ \frac{a^2}{t} - (1 - \beta t) \right]^2 \geq s_1^2 C_\beta. \]

If $a \in I_1$, \( \frac{a^2}{t} - (1 - \beta t) \) can be bounded so that we can bound the second term in $|N_\varepsilon(a, t)|^2$, that is

\[ |N_\varepsilon(a, t)|^2 \geq s_2 \left( \frac{a^2}{t} - (1 - \beta t) - \frac{a}{t} \right)^2 = \left[ O(s_2) - \frac{a}{t} \right]^2 \geq s_1^2 C_\beta \]

whenever $|\varepsilon|$ is sufficiently small. The above estimates for $|N_\varepsilon(a, t)|$ give that

\[ |N_\varepsilon(a, t)| \geq s_1 C_\beta. \]

Therefore,

\begin{equation}
\inf_{a \in \mathbb{R}, t \in \mathbb{Z} \setminus \{0\}} |N_\varepsilon(a, t)| \geq s_1 C_\beta \geq \sigma C_{\beta, \mu}
\end{equation}

for a positive constant $C_{\beta, \mu}$ depending on $\beta$ and $\mu$, by the domain of $\varepsilon \in \Omega(\sigma, \mu)$.

Consequently, for $\tilde{N}_\varepsilon(k, j)$ defined in (7.10), we obtain

\begin{equation}
\sup_{k \in \mathbb{Z}^d, j \in \mathbb{Z} \setminus \{0\}} |\tilde{N}_\varepsilon(k, j)| \leq \sup_{a \in \mathbb{R}, t \in \mathbb{Z} \setminus \{0\}} |N_\varepsilon(a, t)| \leq \sigma^{-1} C_{\beta, \mu}.
\end{equation}

It follows that

\[ \|N_\varepsilon^{-1}(V)\|_{\rho, m} \leq \sigma^{-1} C_{\beta, \mu} \| V \|_{\rho, m-2}. \]

This allows us to define

\[ \|N_\varepsilon^{-1}\|_{\mathcal{H}^{m-2} \rightarrow \mathcal{H}^m} = \sup_{k \in \mathbb{Z}^d, j \in \mathbb{Z} \setminus \{0\}} |\tilde{N}_\varepsilon(k, j)|. \]

That means $\varepsilon N_\varepsilon^{-1}$ can be bounded from $\mathcal{H}^{m-2}$ to $\mathcal{H}^m$. \qed

As a matter of fact, Lemma 25 and Lemma 26 give that the operator $T$ defined in (7.7) is analytic from the space $\mathcal{H}^{\rho, m}$ to itself.

\textbf{Remark 27.} Note that the previous Lemma 26 includes the case of $\varepsilon \in \mathbb{R}$, which will be used in the later finitely differentiable case (see Lemma 29).

Note also that for the equation (7.1), the nonlinearity will always be regular. Therefore, we just consider the finitely differentiable version with $m > \frac{d+1}{2}$. The analogue of the low regularity results for ODE case would be easier to consider.
7.4. Proof of Theorem 23. In this section, we give the proof of Theorem 23.

7.4.1. Regularity in $\varepsilon$. Since we want to obtain solutions depending analytically on $\varepsilon$, proceeding as in Section 5.2, we consider $T := T_\varepsilon$ defined in (7.7) acting on the space $\mathcal{H}^{p,m,\Omega}$ consisting of analytic functions of $\varepsilon$ taking values in $\mathcal{H}^{p,m}$ with $\varepsilon$ ranging over the domain $\Omega(\sigma,\mu)$. We endow $\mathcal{H}^{p,m,\Omega}$ with supremum norm

$$\|U\|_{p,m,\Omega} = \sup_{\varepsilon \in \Omega(\sigma,\mu)} \|U\|_{p,m},$$

which makes $\mathcal{H}^{p,m,\Omega}$ a Banach space. Moreover, it is also a Banach algebra when $m > (d + 1)$. Based on Lemma 26, we show that the operator $T$ maps the space $\mathcal{H}^{p,m,\Omega}$ into itself. The idea of the proof is similar to Lemma 14, but the details are different since PDE model (7.1) involves a space variable $x$.

**Proposition 28.** If $m > (d + 5)$, then the operator $T$ defined in (7.7) maps the analytic Banach space $\mathcal{H}^{p,m,\Omega}$ into itself. Precisely, if the mapping $\varepsilon \rightarrow U_\varepsilon : \Omega \rightarrow \mathcal{H}^{p,m}$ is complex differentiable, then, $\varepsilon \rightarrow T_\varepsilon(U_\varepsilon) : \Omega \rightarrow \mathcal{H}^{p,m}$ is also complex differentiable.

**Proof.** From the fixed point equation (7.7), we know that $T_\varepsilon$ is composed by $\varepsilon \mathcal{N}^{-1}_\varepsilon$ and $h$ defined in Lemma 25. Lemma 25 gives that $h(\mathcal{H}^{p,m,\Omega}) \subset \mathcal{H}^{p,m-2,\Omega}$. Hence, it suffices to verify that $\varepsilon \mathcal{N}^{-1}_\varepsilon(\mathcal{H}^{p,m-2,\Omega}) \subset \mathcal{H}^{p,m,\Omega}$. In the following step, we use a similar method as that in the proof of Proposition 14.

For a fixed $\varepsilon \in \Omega$, we expand $V_\varepsilon(\theta, x) \in \mathcal{H}^{p,m-2}$ as

$$V_\varepsilon(\theta, x) = \sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}\setminus\{0\}} \hat{V}_{k,j,\varepsilon} e^{i(k \cdot \theta + j \cdot x)}$$

with

$$\left|\hat{V}_{k,j,\varepsilon}\right| \leq \|V_\varepsilon\|_{p,m-2} e^{-\rho(|k|+|j|)(|k|^2 + |j|^2 + 1)^{-\frac{m-2}{2}}}
$$

and

$$\left|\frac{d}{d\varepsilon} \hat{V}_{k,j,\varepsilon}\right| \leq \left|\frac{d}{d\varepsilon} V_\varepsilon\right|_{p,m-2} e^{-\rho(|k|+|j|)(|k|^2 + |j|^2 + 1)^{-\frac{m-2}{2}}}.$$

It follows from (7.5) that

$$\varepsilon \mathcal{N}^{-1}_\varepsilon(V_\varepsilon) = \sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}\setminus\{0\}} \varepsilon \mathcal{N}^{-1}_\varepsilon(k \cdot \omega, j) \hat{V}_{k,j,\varepsilon} e^{i(k \cdot \theta + j \cdot x)},$$

where

$$\mathcal{N}^{-1}_\varepsilon(k \cdot \omega, j) = \frac{1}{-\varepsilon(k \cdot \omega)^2 + i(k \cdot \omega) - \varepsilon(\beta j^4 - j^2)} := \mathcal{N}^{-1}_\varepsilon.$$  

By (7.13), one has

$$\left|\frac{d}{d\varepsilon} \left(\varepsilon \mathcal{N}^{-1}_\varepsilon \hat{V}_{k,j,\varepsilon}\right)\right| \leq \left|\mathcal{N}^{-1}_\varepsilon\right| \left|\hat{V}_{k,j,\varepsilon}\right| + \left|\varepsilon \frac{d}{d\varepsilon} \mathcal{N}^{-1}_\varepsilon\right| \left|\hat{V}_{k,j,\varepsilon}\right| + \left|\varepsilon \mathcal{N}^{-1}_\varepsilon\right| \left|\frac{d}{d\varepsilon} \hat{V}_{k,j,\varepsilon}\right| \leq C_{\beta,\mu} \cdot \sigma^{-1} |j|^2 \left(\left|\hat{V}_{k,j,\varepsilon}\right| + \left|\frac{d}{d\varepsilon} \hat{V}_{k,j,\varepsilon}\right|\right).$$
Together with (7.14) and (7.15), we get
\[
\left\| \frac{d}{d\varepsilon} \left( \varepsilon N^{-1}_\varepsilon \hat V_{k,j,\varepsilon} \right) e^{i(k\theta+j \cdot x)} \right\|_{\rho,m-\tau} \\
\leq C_{\beta,\mu} \cdot \sigma^{-1} |j|^2 \left( \|\hat V_{k,j,\varepsilon}\| + \left\| \frac{d}{d\varepsilon} \hat V_{k,j,\varepsilon} \right\| e^{i(k\theta+j \cdot x)} \right) \|e^{i(k\theta+j \cdot x)}\|_{\rho,m-\tau} \\
\leq C_{\beta,\mu} \cdot \sigma^{-1} |j|^2 \left( \|V\|_{\rho,m-2} + \left\| \frac{d}{d\varepsilon} V \right\|_{\rho,m-2} \right) e^{r(\varepsilon^2)} \\
\cdot (|k|^2 + |j|^2 + 1)^{-\frac{m}{2}} e^\rho(|k|+|j|)(|k|^2 + |j|^2 + 1)^{-\frac{m}{2}} \\
\leq C_{\beta,\mu} \cdot \sigma^{-1} \left( \|V\|_{\rho,m-2} + \left\| \frac{d}{d\varepsilon} V \right\|_{\rho,m-2} \right) (|k|^2 + |j|^2 + 1)^{-\frac{m}{2}}.
\]
By choosing \( d + 5 < \tau \leq m \), we obtain that
\[
\sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}^\tau \setminus \{0\}} (|k|^2 + |j|^2 + 1)^{-\frac{m}{2}} \leq C_d \sum_{k=0}^\infty (\kappa^2 + 1)^{-\frac{d+4}{2}} < \infty.
\]
As a consequence, by Weierstrass M-test, we conclude that the series
\[
\sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}^\tau \setminus \{0\}} \frac{d}{d\varepsilon} \left( \varepsilon N^{-1}_\varepsilon \hat V_{k,j,\varepsilon} \right) e^{i(k\theta+j \cdot x)}
\]
converge uniformly on \( \varepsilon \in \Omega \) in the space \( \mathcal{H}^{\rho,m-\tau} \). Therefore,
\[
\frac{d}{d\varepsilon} \left( \varepsilon N^{-1}_\varepsilon (V_\varepsilon) \right) = \sum_{k \in \mathbb{Z}^d, j \in \mathbb{Z}^\tau \setminus \{0\}} \frac{d}{d\varepsilon} \left( \varepsilon N^{-1}_\varepsilon \hat V_{k,j,\varepsilon} \right) e^{i(k\theta+j \cdot x)}.
\]
In conclusion, we have that the map \( \varepsilon \to \varepsilon N^{-1}_\varepsilon (V_\varepsilon) : \Omega \to \mathcal{H}^{\rho,m} \) is complex differentiable with derivatives in \( \mathcal{H}^{\rho,m-\tau} \) by \( \mathcal{H}^{\rho,m} \subset \mathcal{H}^{\rho,m-\tau} \) and Lemma 32 in Appendix.

7.4.2. Proof of Theorem 23. We now start to deal with the fixed point equation
\[
U(\theta, x) = N^{-1}_\varepsilon [\varepsilon (U^2)_{xx} + \varepsilon f(\theta, x)] = T(U)(\theta, x),
\]
in the space \( \mathcal{H}^{\rho,m,\Omega} \). We will find a fixed point of \( T \) by considering a small ball \( B_r(0) \subset \mathcal{H}^{\rho,m,\Omega} \) with \( C_{\beta,\mu} \cdot r < \frac{1}{2} \) such that \( T(B_r(0)) \subset B_r(0) \) and \( T \) is a contraction in this ball.

It follows from Lemma 26 that
\[
\|\varepsilon N^{-1}_\varepsilon \|_{\rho,m,\Omega} \leq C_{\beta,\mu}.
\]
Hence, if \( U \in B_r(0) \), Lemma 25 shows that
\[
\|T(U)\|_{\rho,m,\Omega} \leq \|T(0)\|_{\rho,m,\Omega} + \|T(U) - T(0)\|_{\rho,m,\Omega} \\
\leq \|\varepsilon N^{-1}_\varepsilon \|_{\rho,m,\Omega} (\|f\|_{\rho,m,\Omega} + \|Dh(V)U\|_{\rho,m-2,\Omega}) \\
\leq C_{\beta,\mu} (\|f\|_{\rho,m,\Omega} + \|V\|_{\rho,m,\Omega} \|U\|_{\rho,m,\Omega}) \\
\leq C_{\beta,\mu} (\|f\|_{\rho,m,\Omega} + r^2) \leq r,
\]
provided that we impose the smallness condition for \( f \) satisfying
\[
\|f\|_{\rho,m,\Omega} \leq \frac{r}{2C_{\beta,\mu}}.
\]
Moreover, for \( U_1, U_2 \in \mathbb{B}_r(0) \), we get that
\[
\| T(U_1) - T(U_2) \|_{\rho, m, \Omega} = \| \varepsilon N_{\varepsilon}^{-1} h(U_1) - \varepsilon N_{\varepsilon}^{-1} h(U_2) \|_{\rho, m, \Omega} \\
\leq C_{\beta, \mu} \cdot r \| U_1 - U_2 \|_{\rho, m, \Omega} \\
< \frac{1}{2} \| U_1 - U_2 \|_{\rho, m, \Omega},
\]
which implies that \( T \) is a contraction in the ball \( \mathbb{B}_r(0) \). In conclusion, there is a unique fixed point \( U \) in the space \( \mathcal{H}^{\rho, m, \Omega} \) for equation (7.7). Namely, we obtain a solution \( U_\varepsilon \) analytic in \( \varepsilon \) for equation (7.4). For \( \varepsilon \to 0 \), we have \( \varepsilon \to U_\varepsilon \) is continuous, whose proof is similar to Lemma 17.

7.5. Proof of Theorem 24. In this section, we consider \( T := T_\varepsilon \) defined in (7.7) acting on space \( \mathcal{H}^{m, \Omega} \) consisting of differentiable functions of \( \varepsilon \) taking values in \( \mathcal{H}^m \) with \( \varepsilon \) ranging over the domain \( \tilde{\Omega}(\sigma, \mu) \). We endow \( \mathcal{H}^{m, \Omega} \) with supremum norm
\[
(7.16) \quad \| U \|_{m, \Omega} = \sup_{\varepsilon \in \tilde{\Omega}(\sigma, \mu)} \| U_\varepsilon \|_m.
\]
We only have the result that the space \( \mathcal{H}^m \) is a Banach space and it is also a Banach algebra when \( m > \frac{d+1}{2} \) but not the space \( \mathcal{H}^{m, \Omega} \) with the supremum norm with respect to \( \varepsilon \) defined in (7.16). Consequently, the contraction mapping principle is not enough to get the solution \( U_\varepsilon \) with optimal regularity in \( \varepsilon \). We will combine with the implicit function theorem to obtain the regular solutions.

In order to use the implicit function theorem, analogous to Section 6, the main issue is to study the differentiability of the operator \( T(\varepsilon, U) \) in (7.7) considered as an operator from \( \tilde{\Omega} \times \mathcal{H}^m \) to \( \mathcal{H}^m \) as well as the invertibility of \( D_2 T(\varepsilon, U) \).

We first present the result with respect to the argument \( U \). Since Lemma 25 and Lemma 26 also hold in the finitely differentiable setting, we have the following result when we work in the space \( \mathcal{H}^m \).

Lemma 29. For a fixed \( \varepsilon \in \tilde{\Omega}(\sigma, \mu) \), the operator \( T_\varepsilon \) is analytic from the space \( \mathcal{H}^m \) to itself.

Now, we give the following proposition with the result that the operator \( T \) in (7.7) is differentiable in the argument \( \varepsilon \). Note that \( T \) is composed by \( \varepsilon N_{\varepsilon}^{-1} \) and \( h \) defined in (7.9). Since \( h(\mathcal{H}^m) \subset \mathcal{H}^{m-2} \), we need to verify that the derivatives of \( \varepsilon N_{\varepsilon}^{-1} \) with respect to \( \varepsilon \) is bounded from the space \( \mathcal{H}^{m-2} \) to the space \( \mathcal{H}^m \). Similar to Proposition 18, we have:

Proposition 30. Fix any \( m \in \mathbb{N} \) with \( m > \frac{d+1}{2} \) and \( \sigma > 0 \). We consider the map that to every \( \varepsilon \in \tilde{\Omega} \), \( \varepsilon N_{\varepsilon}^{-1} \in B(\mathcal{H}^{m-2}, \mathcal{H}^m) \). Moreover, for any \( l \in \mathbb{N} \) and \( \varepsilon \in \tilde{\Omega} \), the map \( \varepsilon \rightarrow \varepsilon N_{\varepsilon}^{-1} \) is \( C^l \) considered as a mapping from \( \tilde{\Omega} \) to \( B(\mathcal{H}^{m-2}, \mathcal{H}^m) \).

As a matter of fact, something stronger is true. The mapping \( \varepsilon \rightarrow \varepsilon N_{\varepsilon}^{-1} \) is real analytic for \( \varepsilon \in \tilde{\Omega} \) and the radius of analyticity can be bounded uniformly for all \( \varepsilon \in \tilde{\Omega} \).

Proof. The idea of the proof is similar to Proposition 18. Based on the estimates \( |N_{\varepsilon}(a, t)| \geq \sigma C_{\beta, \mu} \) in (7.12) in Lemma 26, we now expand \( N_{\varepsilon+\delta}^{-1}(a, t) \) in powers of
\( N_{\varepsilon+\delta}(a, t) = \left( (\varepsilon + \delta) \left[ \frac{a^2}{t} - (1 - \beta t) + \frac{a}{t} \right] \right)^{-1} \)

\( = \left( \varepsilon \left[ \frac{a^2}{t} - (1 - \beta t) + \frac{a}{t} \right] - \delta \left[ \frac{a^2}{t} - (1 - \beta t) \right] \right)^{-1} \)

\( = \left( -\varepsilon \left[ \frac{a^2}{t} - (1 - \beta t) + \frac{a}{t} \right] - \delta \left[ \frac{a^2}{t} - (1 - \beta t) \right] \right)^{-1} \)

By the estimates in Lemma 26, we observe that the factor \( \frac{a^2}{t} - (1 - \beta t) + \frac{a}{t} \) is bounded uniformly in \( a \in \mathbb{R}, t \in \mathbb{Z}_+ \) and \( \varepsilon \in \Omega \).

Therefore, we can expand \( \left( 1 - \delta \frac{a^2}{t} - (1 - \beta t) + \frac{a}{t} \right)^{-1} \) in (7.17) in powers of \( \delta \) using the geometric series formula and the radii of convergence are bounded uniformly and the values of the function are also bounded in a ball which is uniform in \( a \in \mathbb{R}, t \in \mathbb{Z}_+ \) and \( \varepsilon \in \Omega \). That means \( N_{\varepsilon}^{-1} \) is uniformly analytic in \( \varepsilon \) for each \( a \in \mathbb{R}, t \in \mathbb{Z}_+ \).

In the Fourier space, we know that \( N_{\varepsilon}^{-1} \) is multiplier operator with the multiplier \( N_{\varepsilon,k,j}^{-1} \). Precisely, for \( \hat{f}_{k,j} \) being the Fourier coefficients of function \( f \) in the space \( \mathcal{H}^{m-2} \), the Fourier coefficients \( \mathcal{N}_{\varepsilon}^{-1}(f)_{k,j} \) of function \( \mathcal{N}_{\varepsilon}^{-1}(f) \) in the space \( \mathcal{H}^m \) have the structure:

\( \mathcal{N}_{\varepsilon}^{-1}(f)_{k,j} = N_{\varepsilon,k,j}^{-1} \hat{f}_{k,j} \).

Hence, we get that \( \mathcal{N}_{\varepsilon}^{-1} \) is analytic in \( \varepsilon \).

Moreover, we can bound \( \|\mathcal{N}_{\varepsilon}^{-1}\|_{\mathcal{H}^{m-2} \to \mathcal{H}^m} \) by the norm defined by

\[
\|\mathcal{N}_{\varepsilon}^{-1}\|_{\mathcal{H}^{m-2} \to \mathcal{H}^m} = \sup_{k \in \mathbb{Z}^d, j \in \mathbb{Z} \setminus \{0\}} \|N_{\varepsilon,k,j}^{-1}\|
\]

since the uniform boundness of \( N_{\varepsilon,k,j}^{-1} \) in \( k \in \mathbb{Z}^d, j \in \mathbb{Z} \setminus \{0\} \). Therefore, when we write \( N_{\varepsilon+\delta}^{-1} = \sum_{n=0}^{\infty} \mathcal{N}_{\varepsilon,n}^{-1} \delta^n \), \( \|\mathcal{N}_{\varepsilon,n}\|_{\mathcal{H}^{m-2} \to \mathcal{H}^m} \) can be bounded by the definition in (7.18). That means \( \frac{d}{d\varepsilon}(\varepsilon \mathcal{N}_{\varepsilon}^{-1}) \in B(\mathcal{H}^{m-2}), \mathcal{H}^m \) for every \( \varepsilon \in \Omega \). \( \Box \)

Now, we start to prove Theorem 24 by constructing a fixed point \( U_{\varepsilon_0} \) for \( \varepsilon_0 \in \tilde{\Omega} \) first and then using the implicit function theorem to obtain the optimal regularity of \( U_\varepsilon \) in \( \varepsilon \). It is similar to the proof in Section 6.1.2. We omit some details here.

**Proof.** First, when we choose a small ball \( B_{\varepsilon}(0) \subset \mathcal{H}^{m,\Omega} \), the similar process to Section 7.4.2 allows us to obtain a fixed point \( U_{\varepsilon_0} \in \mathcal{H}^m \) for some \( \varepsilon_0 \in \tilde{\Omega} \) by the contraction argument in this ball.

Then, according to Lemma 29 and Proposition 30, we obtain that the operator \( \mathcal{T} \) defined on \( \tilde{\Omega} \times \mathcal{H}^m \) is \( C^1 \) in arguments \( \varepsilon \) and \( U \). Namely, \( \mathcal{T}(\varepsilon, U) := U - \mathcal{T}(\varepsilon, U) \) is \( C^1 \) in \( \Omega \times \mathcal{H}^m \). Based on the first step, we have \( \mathcal{T}(\varepsilon_0, U_{\varepsilon_0}) = 0 \). Moreover, \( \mathcal{D}_U \mathcal{T}(\varepsilon_0, U_{\varepsilon_0}) = I d - \varepsilon_0 \mathcal{N}_{\varepsilon_0}^{-1} \mathcal{D}_h(U_{\varepsilon_0}) \) is invertible since \( \varepsilon_0 \mathcal{N}_{\varepsilon_0}^{-1} \mathcal{D}_h(U_{\varepsilon_0}) \) is sufficiently small in a small domain of the origin. Therefore, by
the implicit function theorem, there exist an open neighborhood included in \( \tilde{\Omega} \times \mathcal{H}^m \) of \((U_{\varepsilon_0}, \varepsilon_0)\) and a \( C^1 \) function \( U_{\varepsilon} \) satisfying \( T(\varepsilon, U_{\varepsilon}) = 0 \) on this neighborhood. □

**Appendix A. Some properties in analytic and finitely differentiable Banach spaces**

**A.1. Analytic functions in Banach space.**

**Definition 31.** Let \( X, Y \) be complex Banach spaces and \( O \subset X \) is open. We say that \( f : O \to Y \) is analytic if it is differentiable at all points of \( O \) and there exists a function \( \gamma := \gamma_x(||z||) \), with \( \gamma_x(||z||) \to 0 \) as \( ||z|| \to 0 \), such that
\[
||f(x + z) - f(x) - Df(x) \cdot z|| \leq \gamma_x(||z||)
\]
for all \( x \in O \) and \( z \in X \) such that \((x + z) \in O\).

Note that Definition 31 is a rather weak version of differentiability, but it is enough for this paper. For more analyticity of nonlinear functions in Banach spaces, we refer to [HP74, Muj86].

The main result of this appendix is the theory of complex analytic functions in Banach space, bootstrapping the meaning of derivatives of analytic functions. The result could be deduced from stronger results in [HP74, RS80], but we thought it would be useful to present a self-contained proof since this lemma could be useful in other applications.

**Lemma 32.** Let \( U \subseteq \mathbb{C} \) be open and \( X, Y \) be complex Banach spaces, \( X \subseteq Y \) with continuous embedding. Let \( f : U \to X \), which is differentiable in \( Y \) for all \( x \in U \), and
\[
(A.1) \quad \lim_{h \to 0} \left\| \frac{f(x + h) - f(x)}{h} - f'(x) \right\|_Y = 0.
\]
Then, \( f'(x) \in X \) and
\[
(A.2) \quad \lim_{h \to 0} \left\| \frac{f(x + h) - f(x)}{h} - f'(x) \right\|_X = 0.
\]

We start proving the Cauchy-Goursat theorem for functions satisfying (A.1). The proof is rather straightforward. This will lead to a Cauchy formula, from which we can deduce (A.2).

**Proposition 33.** Let \( g : U \to X \subseteq Y \), be differentiable at everywhere in the sense of \( Y \) differentiable. Let \( \gamma \) be a triangle contour contained in \( U \). Then
\[
\int_{\gamma} g(z)dz = 0.
\]

Of course, by the usual approximation procedures, one can get the result for more general paths. This will not be needed for our purposes. Note that, by the fact that \( g \) is continuous as a function from \( U \) to \( Y \), we know that the integrals over paths involved can be understood as Riemann integrals.

**Proof.** Suppose \( \gamma \) is a triangular contour with positive orientation, we construct four positively oriented contours that are triangles obtained by joining the midpoints of
the sides of \( \gamma \). Then, we have
\[
\int_{\gamma} g(z)dz = \sum_{i=1}^{4} \int_{\gamma_i} g(z)dz.
\]
Let \( \gamma_1 \) be selected such that
\[
\left| \int_{\gamma} g(z)dz \right| \leq \sum_{i=1}^{4} \left| \int_{\gamma_i} g(z)dz \right| \leq 4 \int_{\gamma_1} g(z)dz.
\]
If \( \int_{\gamma} g(z)dz = b \neq 0 \), we get
\[
\left| \int_{\gamma_1} g(z)dz \right| \geq \frac{1}{4} |b|.
\]
Proceeding by induction, we get a sequence of triangular contours \( \{ \gamma_n \} \), whose length equals \( 2^{-n} |\gamma| \), where \( |\gamma| \) denotes the length of \( \gamma \), such that
\[
(A.3) \quad \left| \int_{\gamma_n} g(z)dz \right| \geq \frac{1}{4^n} |b|.
\]
By the choice of \( \gamma_n \), we have
\[
\text{Interior of } \gamma_{n+1} \subset \text{Interior of } \gamma_n
\]
and the length of the sides of \( \gamma_n \) goes to 0 as \( n \to \infty \). Therefore there exists a unique point \( z_0 \in \bigcap_{n} \text{Interior of } \gamma_n \in U \).

Since \( g \) is differentiable at \( z_0 \), there is a function \( R \) such that
\[
g(z) = g(z_0) + g'(z_0)(z - z_0) + R(z, z_0),
\]
where
\[
\| R(z, z_0) \|_Y \leq |z - z_0| w(|z - z_0|)
\]
with \( w(|z - z_0|) \to 0 \) when \( |z - z_0| \to 0 \). Integrating \( g \) along \( \gamma_n \), we find that
\[
\int_{\gamma_n} g(z)dz = \int_{\gamma_n} g(z_0)dz + \int_{\gamma_n} g'(z_0)(z - z_0)dz + \int_{\gamma_n} R(z, z_0)dz
= [g(z_0) - g'(z_0)z_0] \int_{\gamma_n} 1dz + g'(z_0) \int_{\gamma_n} zdz + \int_{\gamma_n} R(z, z_0)dz
= \int_{\gamma_n} R(z, z_0)dz.
\]
Therefore,
\[
\left\| \int_{\gamma_n} g(z)dz \right\|_Y \leq |\gamma_n| \cdot \sup_{z \in \gamma_n} \| R(z, z_0) \|_Y
\]
\[
(A.4) \quad \leq |\gamma_n| \cdot \frac{|\gamma_n|}{2} \cdot w \left( \frac{|\gamma_n|}{2} \right)
\]
\[
\leq \frac{|\gamma|^2}{2 \cdot 4^n} w \left( \frac{|\gamma_n|}{2} \right)
\]
by \( |z - z_0| < \frac{1}{2} |\gamma_n| \) for \( z \in \gamma_n \). Comparing (A.3) and (A.4), we get \( b = 0 \) as desired. \( \square \)
As a corollary, we obtain the same conclusion, but assuming only that \( g \) is differentiable at all points inside of the triangle except for the center of the small triangles.

Now we begin to prove Lemma 32. As it is standard, for the function \( f \) in Lemma 32, fix \( \epsilon \) belonging to interior of \( \gamma \), we define

\[
g_{\epsilon}(z) = \begin{cases} 
\frac{f(z) - f(\epsilon)}{z - \epsilon}, & z \neq \epsilon, \\
f'(z), & z = \epsilon,
\end{cases}
\]

which satisfies the hypothesis of the Proposition 33 or its corollary. If \( \gamma \) is an triangle centered at \( \epsilon \), then

\[
0 = \int_{\gamma} g_{\epsilon}(z)dz = \int_{\gamma} \frac{f(z)}{z - \epsilon}dz - f(\epsilon) \int_{\gamma} \frac{1}{z - \epsilon}dz.
\]

Hence we satisfy the formula

\[
f(\epsilon) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{z - \epsilon}dz.
\]

Now, we can compute the derivative with respect to \( \epsilon \) in space \( X \) and obtain

\[
f'(\epsilon) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{(z - \epsilon)^2}dz.
\]

Of course, since the derivative is obtained as limits of quotients, if the limit exists in \( X \), it has to agree with the limit in \( Y \).

A.2. Finitely differentiable functions in Banach space. For arbitrary Banach spaces \( X_1, \cdots, X_i, Y, i \geq 1 \), we denote by \( A(X^{\otimes i}, Y) \) the space of symmetric continuous \( i \)-linear forms on \( X^{\otimes i} := X_1 \times \cdots \times X_i \) taking values in \( Y \). Now we present the converse to Taylor’s theorem (see page 6 in the book [AR67]).

**Lemma 34.** Let \( O \subset X \) be a convex set and \( F: O \to Y, f_i: O \to A(X^{\otimes i}, Y), i = 0, \cdots, r \). For any \( x \in O \) and \( h \in X \) such that \( (x + h) \in O \), we define \( R(x,h) \) by

\[
F(x + h) = F(x) + \sum_{i=1}^{r} \frac{f_i(x)(h, \cdots, h)}{i!} + R(x,h).
\]

If for any \( 0 \leq i \leq r \), \( f_i \) is continuous and for any \( x \in O \), \( \|R(x,h)\|_Y \to 0 \) as \( \|h\|^r_X \to 0 \), then we say \( F \) is of class \( C^r \) on \( O \) and \( D^i F = f_i \) for any \( 0 \leq i \leq r \).

**Definition 35.** We denote by \( C^r(O,Y) \) the space of functions \( f: O \to Y \) with continuous derivatives up to order to \( r \). We endow \( C^r(O,Y) \) with the norm of the supremum of all the derivatives. Namely,

\[(A.5) \quad \|f\|_{C^r} = \max_{0 \leq i \leq r} \sup_{x \in O} \|D^i f(x)\|_{X^{\otimes i}, Y} \]

with

\[
\|\cdot\|_{X^{\otimes i}, Y} = \sup_{\|x_1\|_{X_1} = \cdots = \|x_i\|_{X_i} = 1} \|A(x_1, \cdots, x_i)\|_Y.
\]

As it is well known, the norm \((A.5)\) makes \( C^r(O,Y) \) a Banach space.
Definition 36. We denote by $C^{r+Lip}(O,Y)$ the space of functions in $C^r(O,Y)$ whose $r$ th derivative is Lipschitz. The Lipschitz constant is

$$\text{Lip}_{O,Y} D^r f = \sup_{x_1, x_2 \in X, x_1 \neq x_2} \frac{|D^r f(x_1) - D^r f(x_2)|_{X^{\otimes r},Y}}{\|x_1 - x_2\|_X}.$$ 

We note that since $O$ may be not compact, this definition is different from the Whitney definition in which the topology is given by semi-norms of supremum in compact sets. We will not use the Whitney definition of $C^r$ in this paper.

Definition 37. An open set $O$ is called a compensated domain if there is a constant $C$ such that given $x,y \in O$ there is a $C^1$ path $\gamma$ contained in $O$ joining $x,y$ satisfying $|\gamma| \leq C \|x - y\|_X$.

For $O$ a compensated domain, we have the mean value theorem

$$\|f(x) - f(y)\|_Y \leq C \|f\|_{C^1(O,Y)} \|x - y\|_X.$$ 

In particular, $C^1$ functions in a compensated domain are Lipschitz. It is not difficult to construct non-compensated domains with $C^1$ functions which are not Lipschitz.

Of course a convex set is compensated and the compensation constant is 1. In our paper, we will just be considering domains which are balls or full spaces. See [dlLO99] for the effects of the compensation constants in many problems of the function theory.

A.3. The standard Sobolev space. As a matter of fact, we define

$$H^m(T^d) := H^m(T^d,\mathbb{R}^n) := \{ U = (U_1, \ldots, U_n) | U_i \in H^m(T^d,\mathbb{R}), i = 1, \ldots, n \}$$

equipped with the norm

(A.6) $\|U\|_{H^m} = \sum_{0 \leq |\alpha| \leq n} \|U_\alpha\|_{H^m}$.

And

$$H^m(T^d,\mathbb{R}) = \{ U \in L^2(T^d,\mathbb{R}) : D^{\alpha}|U| \in L^2(T^d,\mathbb{R}), \ 0 \leq |\alpha| \leq m \},$$

where we use multi-index notation $\alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}^d, |\alpha| = \sum_{i=1}^d \alpha_i$ and $x = (x_1, \ldots, x_d) \in T^d$, $D^{\alpha} := D^{\alpha_1}_{x_1} \cdots D^{\alpha_d}_{x_d}$. We define

$$\|U\|_{H^m(T^d,\mathbb{R})} = \sum_{0 \leq |\alpha| \leq m} \|D^{\alpha}U\|_{L^2}$$

with

$$\|U\|_{L^2} = \left( \int_{T^d} |U(\theta)|^2 d\theta \right)^{\frac{1}{2}}.$$ 

Indeed, by Fourier transformation, the norm defined in (A.6) is equivalent to the norm defined by Definition 1 based on the Fourier coefficients. We refer to the book [AF03, Tay97] for more details.
